Abstract: The Cladosporium herbarum complex comprises five species for which Davidiella teleomorphs are known. Cladosporium herbarum s. str. (D. fassiana), C. macrocarpum (D. macrocarpa) and C. brunnei (D. allicina) are distinguishable by having conidia of different width, and by teleomorph characters. Davidiella variabile is introduced as teleomorph of C. variable, a homothallic species occurring on Spinacia, and D. macrospora is known to be the teleomorph of C. indis on Iris spp. The C. herbarum complex combines low molecular distance with a high degree of clonal or inbreeding diversity. Entities differ from each other by multilocus sequence data and by phenetic differences, and thus can be interpreted to represent individual taxa. Isolates of the C. herbarum complex that were formerly associated with opportunistic human infections, cluster with C. brunnei. Several species are newly described from hypersaline water, namely C. ramotenellum, C. tenellum, C. subinflatum and C. herbaroides. Cladosporium pseudiridis collected from Iris sp. in New Zealand, is also a member of this species complex and shown to be distinct from C. indis that occurs on this host elsewhere in the world. A further new species from New Zealand is C. sinuosum on Fuchsia excorticata. Cladosporium antarcticum is newly described from a lichen, Caloplaca regalis, collected in Antarctica, and C. subtilissimum from grape berries in the U.S.A., while the new combination C. ossifiagr, the oldest valid name of the Cladosporium known from Narthecium in Europe, is proposed. Standard protocols and media are herewith proposed to facilitate future morphological examination of Cladosporium spp. in culture, and neotypes or epitypes are proposed for all species treated.

Key words: Clonality, Davidiella, homothallism, new species, phylogeny, recombination, taxonomy.

INTRODUCTION

Cladosporium herbarum (Pers.: Fr.) Link, type species of the genus Cladosporium Link, is one of the most common environmental fungi to be isolated worldwide. It abundantly occurs on fading or dead leaves of herbaceous and woody plants, as secondary invader on necrotic leaf spots, and has frequently been isolated from foodstuffs, paints, textiles, humans (de Hoog et al. 1998, 1999) examined C. herbarum in culture and published detailed descriptions of its features in vitro.

Cladosporium macrocarpum Preuss, a second component within the herbarum complex, has hitherto been known and treated as an allied, but morphologically distinct species on the basis of its wider and somewhat larger, frequently 2–3-septate, more regularly verrucose conidia, shorter conidial chains and more pronounced prolongations of the conidiophores. Dugan & Roberts (1994) carried out examinations of morphological and reproductive aspects of both species, and in so doing demonstrated a morphological continuum between C. macrocarpum and C. herbarum, concluding that the name herbarum should have preference. Therefore, Ho et al. (1999) introduced the new combination C. herbarum var. macrocarpum (Preuss) M.H.M. Ho & Dugan. Although transitional forms have been discussed to occur between the two species, several authors still prefer to retain C. macrocarpum as a separate species.

In an attempt to elucidate the species within the C. herbarum complex, therefore, a multilocus DNA sequence typing approach was used, employing five genes, namely the internal transcribed spacers of the rDNA genes (ITS), actin, calmodulin, translation elongation factor 1-α, and histone H3. These data were supplemented with morphological examinations under standardised conditions, using light and scanning electron microscopy, as well as cultural characteristics and growth studies.

MATERIAL AND METHODS

Isolates

Isolates included in this study were obtained from the culture collection of the Centraalbureau voor Schimmelcultures (CBS), Utrecht, Netherlands, or were freshly isolated from a range of different substrates. Single-conidial and ascospore isolates were obtained using the techniques as explained in Crous (1998) for species of Mycosphaerella Johanson and its anamorphs. Isolates

available online at www.studiesinmycology.org

doi:10.3114/sim.2007.58.05

were inoculated onto 2% potato-dextrose agar (PDA), synthetic nutrient-poor agar (SNA), 2% malt extract agar (MEA) and oatmeal agar (OA) (Gams et al. 2007), and incubated under continuous near-ultraviolet light at 25 °C to promote sporulation. All cultures obtained in this study are maintained in the culture collection of the CBS (Table 1). Nomenclatural novelties and descriptions were deposited in MycoBank (www.Mycobank.org).

DNA isolation, amplification and sequence analysis

Fungal colonies were established on agar plates, and genomic DNA was isolated as described in Gams et al. (2007). Partial gene sequences were determined as described by Crous et al. (2006) for actin (ACT), calmodulin (CAL), translation elongation factor 1-alpha (EF), histone H3 (HIS) and part (ITS) of the nuclear rDNA operon spanning the 3′ end of the 18S rRNA gene (SSU), the first internal transcribed spacer, the 5.8S rRNA gene, the second internal transcribed spacer and the 5′ end of the 28S rRNA gene (LSU). The nucleotide sequences were generated using both PCR primers to ensure good quality sequences over the entire length of the amplicon. Subsequent sequence alignment and phylogenetic analysis followed the methods of Crous et al. (2006). Gaps longer than 10 bases were coded as single events for the phylogenetic analyses; the remaining gaps were treated as new character states. Sequence data were deposited in GenBank (Table 1) and the alignment and tree in TreeBASE (www.treebase.org).

Data analysis

The number of entities in the dataset of 79 strains was inferred with STRUCTURE v. 2.2 software (Pritchard et al. 2000, Falush et al. 2003) using an UPGMA tree of data of the ACT gene compared with CAL, EF and HIS with the exclusion of the nearly invariant ITS region. For this analysis group indications were derived from a tree produced with MrBayes (Nylander 2004). The length of the burn-in period was set to 1,000,000, number of MCMC repeats after burn-in 10,000, with admixture ancestry and allele frequencies correlated models, assuming that all groups diverged from a recent ancestral population and that allele frequencies are due to drift. Uniform prior for ALPHASE III was set to 1.0 (default) and allele frequencies with λ set to 1.0 (default). The numbers of MCMC repetitions after burn-in were set as 10,000 and 100,000. The number of clusters (K) in STRUCTURE was assumed from 5 to 7. Population differentiation FST (index: θ) was calculated with 1–6 runs using the same software. The null hypothesis for this analysis is no population differentiation. When observed theta (θ) is significantly different from those of random data sets (p < 0.05), population differentiation is considered.

Association of multilocus genotypes was screened with the multi locus option in BioNUMERICS v. 4.5. To test for reproductive mode in each population, the standardised index of association \( F_{ST}^{PA} \) (Hautbold et al., 1998) was calculated with START2 software (Jolley et al. 2001). The null hypothesis for this analysis is complete panmixia. The values of \( F_{ST}^{PA} \) were compared between observed and randomised datasets. The hypothesis would be rejected when p < 0.05. Mean genetic diversity (H) and diversities of individual loci were calculated with LIAN v. 3.5 (Hautbold & Hudson 2000). Degrees of recombination or horizontal gene transfer were also visualised using SPLITSTREE v. 4.8 software (Huson & Bryant 2006). Split decomposition was carried out with default settings, i.e., character transformation using uncorrected (observed, \( P^* \)) distances, splits transformation using “equal angle”, and optimise boxes iteration set to 2.

Morphology

As the present study represents the first in a series dealing with Cladosporium spp. by Crous et al. (2007). To study conidial development and branching patterns, squares of transparent adhesive tape (Titan Ultra Clear Tape, Conglom Inc., Toronto, Canada) were placed on conidiophores growing in the zone between the colony margin and 2 cm inwards, and mounted between two drops of Shear’s solution under a glass coverslip. Different types of conidia are formed by Cladosporium species for which different terms need to be adopted. Ramoconidia are conidia with usually more than one (mostly 2 or 3) conidial hilum, which typically accumulate at the tip of these conidia. Conidigenous cells with more than one conidigenous locus are first formed as apical parts of conidiophores. Such apical

Chlamydospores are referred to as "ramoconidia" when they are formed in the context of conidiogenesis and with either a single (when formed as intercalary units in unbranched parts of chains) or without any distal conidial hilum (when formed at the tip of conidial chains). For the first, the term "intercalary conidium" and for the latter, "small terminal conidium" is used. Intercalary conidia typically are larger and more pigmented and have a more differentiated surface ornamentation than the small terminal conidia. In older literature true ramoconidia were often cited as "ramoconidia s. str.,” whereas secondary ramoconidia have been referred to as “ramoconidia s. lat.”

**Morphology of the teleomorph:** Telemorphs were induced by inoculating plates of 2 % tap water agar onto which autoclaved stem pieces of *Urtica dioica* (European stinging nettle) were placed. Inoculated plates were incubated on the laboratory bench for 7 d, after that period they were further incubated at 10 °C in the dark for 1–2 mo to stimulate teleomorph development. Wherever possible, 30 measurements (× 1 000 magnification) were made of conidia and ascospores, with the extremes of spore measurements given in parentheses. Cultural characteristics: Colonies were cultivated on PDA, MEA and OA plates for 14 d at 25 °C in the dark, after which the surface and reverse colours were rated using the charts of Rayner (1970). Linear growth was determined on MEA, PDA and OA plates by inoculating three plates per isolate for each medium, and incubating them for 14 d at 25 °C, after that period colony diameters were determined.

**Low-temperature scanning electron microscopy**

Isolates of *Cladosporium* spp. were grown on SNA with 30 g agar/L for 3–4 d at room temperature under black light. Relevant parts of the small colonies with conidiophores and conidia were selected until now have the ability to form true ramoconidia. Secondary ramoconidia also have more than one distal conidial hilum but they always derive from a conidiogenous locus of an earlier formed cell, which can be either a conidiogenous cell or a ramoconidium. Secondary ramoconidia are often shorter but somewhat wider than ramoconidia; they are often septate, and typically have a narrowed base with a coronate hilum (Fig. 1). Conidia in *Cladosporium* are cells with a coronate basal hilum, which is formed in the context of conidiogenesis and with either a single (when formed as intercalary units in unbranched parts of chains) or without any distal conidial hilum (when formed at the tip of conidial chains). For the first, the term "intercalary conidium" and for the latter, "small terminal conidium" is used. Intercalary conidia typically are larger and more pigmented and have a more differentiated surface ornamentation part of conidiophores are called *ramoconidia* if they secede at a septum from the conidiophore (Kirk et al. 2001). The septum at which the ramoconidium secedes often appears to be somewhat refractive or darkened. Ramoconidia are characterised by having a truncate, undifferentiated base (thus they lack a differentiated, coronate basal hilum formed in the context of conidiogenesis) and they can be very long, aseptate to sometimes multi-septate. Although they were formed initially as part of the conidiophore, they function as propagules. Only few of the species known until now have the ability to form true ramoconidia. Secondary *ramoconidia* also have more than one distal conidial hilum but they always derive from a conidiogenous locus of an earlier formed cell, which can be either a conidiogenous cell or a ramoconidium. Secondary ramoconidia are often shorter but somewhat wider than ramoconidia; they are often septate, and typically have a narrowed base with a coronate hilum (Fig. 1). Conidia in *Cladosporium* are cells with a coronate basal hilum, which is formed in the context of conidiogenesis and with either a single (when formed as intercalary units in unbranched parts of chains) or without any distal conidial hilum (when formed at the tip of conidial chains). For the first, the term "intercalary conidium" and for the latter, "small terminal conidium" is used. Intercalary conidia typically are larger and more pigmented and have a more differentiated surface ornamentation than the small terminal conidia. In older literature true ramoconidia were often cited as “ramoconidia s. str.,” whereas secondary ramoconidia have been referred to as “ramoconidia s. lat.”

**RESULTS**

**Phylogeny and differentiation**

The manually adjusted alignment contained 80 sequences (including the outgroup sequence) and the five loci were represented by a total of 1 516 characters including alignment gaps which were used in the analysis. Of the 1 516 characters, 369 were parsimony-informative, 259 were variable and parsimony-uninformative, and 888 were constant.

Forty equally most parsimonious trees (TL = 1 933 steps; CI = 0.569; RI = 0.786; RC = 0.447), one of which is shown in Fig. 3, were obtained from the parsimony analysis of the combined genes. Neighbour-joining analysis using three substitution models (uncorrected “p”, Kimura 2-parameter and HKY85) on the sequence data yielded trees with identical topologies. These differed from the tree presented in Fig. 3 with regard to the placement of *C. macrocarpum* strain CPC 12054 which was placed as a sister branch to the *C. bruhnei* Linder clade in the distance analyses (results not shown) because it shares an identical CAL sequence.

The intraspecific variation in the C. bruhnei clade is due to genetic variation present in the sequence data of all loci except for ITS, those in the C. macrocarpum clade in all loci except for ITS and ACT, and those in the C. herbarum clade in all loci except for ITS and ACT. None of the variation for these species could be linked to host specificity or morphological differences. In general, ITS data did not provide any resolution within the C. herbarum complex, whereas EF data provided species clades with very little intraspecific variation and ACT, CAL and HIS revealed increasing intraspecific variation (ACT the least and HIS the most).

The mean genetic diversity (H) of the entire data set excluding the nearly invariant ITS region was 0.9307, with little difference between genes (ACT = 0.9257, CAL = 0.9289, EF = 0.9322, HIS = 0.9361). The loci showed different numbers of alleles (ACT: 22, CAL: 16, EF: 21, HIS: 20, ITS: 6). Differentiation of entities when calculated with Structure software using the admixture/correlated model showed highest value with K = 6. At this value FST varied between 0.1362 and 0.3381. Linkage disequilibrium calculated using the standardised index of association (I\textsubscript{SA}) for the entire dataset (observed variance V\textsubscript{o} = 0.5602, expected variance V\textsubscript{e} = 0.2576) was 0.3914 (P = 0.0001), consistent with a small amount of recombination that did not destroy the linkage between alleles. Only few groups appeared to be separated for all alleles; degrees of gene flow are indicated in Fig. 4. SplitStree software produced unresolved star-shaped structures for all genes, without any sign of reticulation (Fig. 5).

Ex-type cultures.
Fig. 3. One of 40 equally most parsimonious trees obtained from a heuristic search with 100 random taxon additions of the combined sequence alignment (ITS, ACT, CAL, EF, HIS). The scale bar shows ten changes, and bootstrap support values from 1000 replicates are shown at the nodes. Thickened lines indicate the strict consensus branches and strain numbers in bold represent ex-type sequences. The tree was rooted to sequences of Cercospora beticola strain CPC 11557 (GenBank accession numbers AY840527, AY840458, AY840425, AY840494, AY840392, respectively).
Fig. 4. Distance tree of the Cladosporium herbarum complex based on ACT sequence data generated with UPGMA, showing STRUCTURE analysis at K = 6 under admixture model with correlated allele frequencies. Group indications (18) are taken from a tree based on EF sequences with AIC under the HKY model.
Morphological features used in the key to distinguish the species treated in this study were determined after 7 d growth at 25 °C on SNA using light microscopy, and cultural characteristics after 14 d incubation on PDA.

1. Conidia usually smooth, rarely minutely verruculose ................................................................. C. cladosporioides (species complex)
2. Conidia with different surface ornamentation, minutely to distinctly verruculose, verrucose to echinulate or spiny ......................................................... 2

2. Conidiophores uniform, macronematous; conidia solitary, sometimes formed in short unbranched chains ................................................................. 3
3. Conidiophores both macronematous and micronematous; conidia always catenate, usually formed in branched chains ......................................................... 5

Fig. 5. Split decomposition of the Cladosporium herbarum complex using SplitsTree of 16–22 unique alleles obtained from 79 Cladosporium isolates for four loci. The star-like structures suggest clonal development. A = ACT, B = CAL, C = HIS, D = EF. Scale bars = 0.01 nucleotide substitutions per site.
3. Conidiophores due to geniculations often growing zigzag-like, (4–)5–7 µm wide; conidia 9–21 × (5–)6–8 µm, 0–1-septate; conidiogenous loci and conidial hila 1.2–2(–2.2) µm diam ................................................................. C. sinuosum
4. Conidia (18–)30–75(–87) × (7–)10–16(–18) µm, (0–)2–6(–7)-septate, walls thickened, especially in older conidia, up to 1 µm thick ........................................................................................................ C. iridis

5. Macronematous conidiophores nodulose or nodose with conidiogenous loci usually confined to swellings ................................................................. 6
6. Macronematous conidiophores non-nodulose or only occasionally subnodulose due to geniculate proliferation, but conidiogenous loci not confined to swellings ........................................................................ 11
7. Macronematous conidiophores 3–6 µm wide, swellings 5–11 µm wide .......................................................................................................................... 7
8. Macronematous conidiophores somewhat narrower, (1.5–)2.5–5 µm wide, swellings 3–8 µm wide ................................................................. 8
9. Conidia formed by macronematous conidiophores not becoming wider and darker with age, usually up to 7 µm wide ................................................................. 10
10. Conidiophores usually with small head-like swellings, sometimes also with a second intercalary nodule; small terminal conidia 4–9 × 2.5–3.5 µm, secondary ramoconidia and occasionally formed ramoconidia 10–24(–31) × 3–5(–7) µm ................................................................. C. bruheii
12. Mycelium dimorphic, narrow hyphae 1–3 µm wide, hyaline to subhyaline, thin-walled, hyphae of the second type wider, 3.5–8(–9) µm, pale to dark greyish olivaceous or olivaceous-brown, thick-walled, sometimes even two-layered, 1(–1.5) µm thick, hyphae appearing consistently enveloped in polysaccharide-like material or covered by a slime coat; conidiophores usually several times slightly to distinctly geniculate towards the apex, with numerous conidiogenous loci crowded towards the apex, up to 14 per conidiogenous cell ................................................................. C. antarcticum
13. Mycelium not dimorphic, neither enveloped in polysaccharide-like material nor covered by a slime coat; conidiophores usually not geniculate, occasionally only slightly so ........................................................................................................... 13
14. Small terminal conidia narrowly obovoid, limoniform or fusiform, but neither globose nor subglobose; conidiogenous loci and conidial hila 0.5–2–(2.5) µm diam ................................................................. C. subtilissimum (species complex)
15. Numerous small globose or subglobose terminal conidia formed, also ovoid or limoniform; conidiogenous loci and conidial hila somewhat smaller, 0.5–1.5(–2) µm diam ................................................................. 15
15. Conidiophores usually with numerous conidiogenous loci forming sympodial clusters of pronounced scars at the apex, sometimes up to 10 or even more denticulate loci; conidia 3–20(–28) × 2.5–5(–6) µm, 0–1(–2)-septate, often with several apically crowded hila, up to 7(–9) µm diam. 

15. Conidiophores usually only with few conidiogenous loci, mostly 1–3; conidia longer and narrower, 2.5–35 × 2–4(–5) µm, 0–3-septate, usually with up to three distal conidial hila. 

C. tenellum

C. ramotenellum

Key to the Davidiella species treated

1. Ascospores frequently wider than 7 µm when mounted in Shear’s solution or lactic acid, apical cell obtusely rounded, ascospores (22–)25–27 µm (30) × (5.5–)6–7 µm................................. D. allicina

1. Ascospores not wider than 7 µm when mounted in Shear’s solution or lactic acid, apical cell acutely rounded, ascospores (20–)25–27 µm (30) × (5.5–)6–7 µm................................. D. macrocarpa

2. Pseudoparaphyses prominent; ascospores frequently >95 µm; ascospores (22–)26–28(–6) × (6–)6.5–7(–8) µm............................ D. variabile

2. Pseudoparaphyses mostly absent in older ascocarps; ascospores <95 µm.............................. D. tassiana

3. Ascospores (22–)26–30(–35) × (7–)7.5–8.5(–9) µm; ascospores not wider than 18 µm............................. D. variabile

3. Ascospores (17–)20–23(–25) × (6–)7(–8) µm; asci not wider than 18 µm............................. D. tassiana

3. Ascospores (22–)26–30(–35) × (7–)7.5–8.5(–9) µm; asci wider than 18 µm. 

1. Ascospores not wider than 7 µm when mounted in Shear’s solution or lactic acid, apical cell acutely rounded, ascospores (20–)25–27(–30) × (5.5–)6–7 µm................................. D. allicina

Generic concept of the teleomorph

The introduction of the teleomorph genus Davidiella was mainly based on phylogenetic studies within the Mycosphaerellaceae (Braun et al. 2003), where it could be demonstrated that “Mycosphaerella” species with Cladosporium anamorphs formed a sister clade to Mycosphaerella (Crous et al. 2000, 2001). Braun et al. (2003) transferred five species to Davidiella based on prior established anamorph-teleomorph connections, though no details were provided pertaining to morphological differences between Davidiella and Mycosphaerella. Aptroot (2006) transferred several additional species to Davidiella, and distinguished them from true Mycosphaerella species by the presence of distinct, irregular cellular inclusions (lumina) in their ascospores. Furthermore, Schoch et al. (2006) placed Davidiella in a separate family (Davidiellaceae) in the Capnodiales. During the course of the present study, several fresh specimens of Davidiella spp. were collected or induced in culture, making it possible to circumscribe the genus as follows:

Ascomata pseudothecial, black to red-brown, globose, inconspicuous and immersed beneath stoma to superficial, situated on a reduced stroma, with 1(–3) short, periphysoidal ostiolar necks; periphysoids frequently growing down into cavity; wall consisting of 3–6 layers of textura angularis. Ascii fasciculate, short-stalked or not, bitunicate, subseptose, obvoid to broadly ellipsoid or subcylindrical, straight to slightly curved, 8-spored. Pseudoparaphyses frequently present in mature ascocarps, hyaline, septate, subcylindrical. Ascospores bi- to multiserialate, hyaline, obvoid to ellipsoid-fusiform, with irregular lumina inclusions, mostly thick-walled, straight to slightly curved; frequently becoming brown and verruculose in ascii; at times covered in mucoid sheath. Cladosporium anamorph usually produced in culture, but not in all taxa.

Description of Cladosporium species

Based on morphological examinations (David 1997) and phylogenetic studies employing DNA sequence data (Crous et al. 2000, 2001, 2007 – this volume, Braun et al. 2003), the generic concept of the genus Cladosporium has been stabilised. Cladosporium is confined to Davidiella (Davidiellaceae, Capnodiales) anamorphs with conurate conidiogenous loci and conidial hila consisting of a central convex dome and a raised periclinal rim.

Etymology: Refers to Antarctica, where the fungus was collected.

Differt a Cladosporio licheniphilo conidiophoris saepe non-ramosis, frequentibus geniculis, angustioribus, (2–)3–4.5 µm, conidiis longioribus et angustioribus, 4–30 × 2.5–5 µm, 0–3-septatis, verruculosis vel verrucosis.

Myelium immersed and superficial, dimorphic, branched, often with short lateral outgrowths, narrow hyphae 1–3 µm wide, hyaline to subhyaline, thin-walled, hyphae of the second type wider, 3.5–8(–9) µm, pluriseptate, often somewhat constricted at the septa, sometimes swollen, pale to dark greyish olivaceous or olivaceous-brown, smooth or verruculose, thick-walled, sometimes even two-layered (two distinct wall layers visible), 1–(1.5) µm thick, hyphae appearing consistently enveloped in polysaccharide-like material or covered by a slime coat. Conidiophores micronematous and macronematous, solitary or in loose groups, arising from plagiotropous or ascending hyphae, terminally or usually laterally. Macronematous conidiophores erect to somewhat decumbent, straight to somewhat flexuous or bent, cylindrical, once or several times slightly to distinctly geniculate towards the apex due to sympodial proliferation, unbranched or once branched, up to 120 µm long, 3–4.5 µm wide, sometimes slightly attenuated towards the apex, pluriseptate, up to eight septa, occasionally slightly constricted at the septa, pale to medium or even dark olivaceous-brown or greyish brown, paler towards apices, smooth to somewhat rough-walled, walls thickened but thinner-walled towards apices, sometimes slightly swollen at the base, up to 6 µm wide. Conidigenous cells integrated, terminal and intercalary, once or several times slightly to distinctly geniculate, 10–33 µm long, proliferation sympodial, with several or numerous conidigenous loci, at first terminal, later turning to one side of the stalk and situated on small lateral shoulders, up to 14 per cell, protuberant, denticulate, 1–1.5(–2) µm diam, thickened and darkened-refractive. Micronematous conidiophores as short lateral, peg-like outgrowths with a single apical scar or somewhat longer, occasionally once

115
Fig. 6. Cladosporium antarcticum (CBS 690.92). Macro- and micronematous conidiophores and conidia. Scale bar = 10 µm. K. Schubert del.

geniculate with several conidiogenous loci at the apex, 2–22 × 2–3 µm, pale greyish olivaceous, loci denticulate. Ramoconidia occasionally occurring, cylindrical, up to 30 µm long, 4–5 µm wide, 0–1-septate, concolorous with the tips of conidiophores, with a broadly truncate, unthickened and not darkened base, without dome and rim, 2.5 µm wide. Conidia catenate, in branched chains, straight, small terminal conidia obvoid, limoniform or narrowly ellipsoid, 4–14 × 2.5–4 µm (av. ± SD, 8.5 (± 3.3) × 3.5 (± 0.6)), 0(−1)-septate, secondary ramoconidia ellipsoid to cylindrical, often with several or numerous conidial hila crowded at the distal end, up to 12, 13–30 × 4–5 µm (av. ± SD, 20.1 (± 5.8) × 4.3 (± 0.5) µm), 0–3-septate, sometimes slightly constricted at the median septum, pale olivaceous-brown or greyish brown, minutely verruculose to verrucose (granulate under SEM), walls more or less thickened, rounded or slightly attenuated towards apex and base, hila protuberant, denticulate, 0.8–1.5(−2) µm diam, thickened and darkened-refractive; microcyclic conidiogenesis occurring.

Cultural characteristics: Colonies on PDA attaining 9 mm diam after 14 d at 25 ºC, greenish olivaceous to grey-olivaceous, at the margin becoming dull green, reverse with a pale olivaceous-grey centre and a broad olivaceous-black margin, margin narrow, regular, entire edge, white, feathery, aerial mycelium sparse but colonies appearing fealty, growth flat with somewhat elevated colony centre, prominent exudates not formed, sporulation dense, covering almost the whole colony. Colonies on OA attaining 4 mm after 14 d at 25 ºC, olivaceous-grey, aerial mycelium sparse, diffuse, growth flat, without prominent exudates, sporulating.

Specimen examined: Antarctica, King George, Arctowski, isolated from the lichen Caloplaca regalis (Teloschistaceae), C. Möller, No. 32/12, 1991, CBS-H 19857, holotype, isotype HAL 2024 F, culture ex-type CBS 690.92.

Substrate and distribution: On the lichen Caloplaca regalis; Antarctica.

Notes: This is the second genuine lichenicolous species of the genus Cladosporium. Cladosporium lichenophilum Heuchert & U. Braun, occurring on apothecia of Pertusaria alpina in Russia, is quite distinct from C. antarcticum by having subcylindrical or only slightly geniculate-sinuous, wider conidiophores, 5–8 µm, with numerous characteristic terminal branches and much shorter, 0–1-septate, smooth conidia, 3.5–13 × 3–7 µm (Heuchert & Braun 2006). Cladosporium lichenicola Linds. was invalidly published and C. arthoniae M.S. Christ. & D. Hawksw. as well as C. lichenum Keissl. are to be excluded from the genus Cladosporium since they do not possess the typical cladosporioid scar structure but inconspicuous, unthickened conidiogenous loci and conidial hila (Hawksworth 1979, Heuchert et al. 2005). The fungicolous species C. uredinicola Speg, and the foliicolous species C. alneum Pass. ex K. Schub. and C. psoraleae M.B. Ellis are morphologically superficially similar. However, C. uredinicola, a widespread fungus on rust fungi, downy mildews and powdery mildew fungi, differs in having somewhat longer and wider, smooth conidia, 3–39 × 2–6.5(−8) µm, and wider conidiogenous loci and conidial hila, 0.5–3...
Cladosporium herbarum

Fig. 7. Cladosporium antarcticum (CBS 690.92). A. Overview of the growth pattern on SNA. Note the very large bulbous cells formed at the base of different conidiophores. Other conidiophores sprout from the agar surface. B. Overview of conidiophores and conidia. Note the large distance of the scars on the conidiophore and the different stages of conidial formation on the tips of other conidia. The long secondary ramoconidia are also visible, and sparse aerial hyphae. C. Detail of B with details of the ornamentation and scars. The absence of ornamentation at the apical (spore-forming) end of the secondary ramoconidium is clearly visible. D–E. Tubular structures on conidiophore (D) and secondary ramoconidium (E). Scale bars: A–B = 10 μm, C–D = 5 μm, E = 2 μm.

μm (Heuchert et al. 2005); C. alneum, which causes leaf spots on Alnus glutinosa, possesses longer and wider conidiophores, 25–260 × (2–)3–7(–8.5) μm, and somewhat shorter, smooth conidia (Schubert 2005, Schubert et al. 2006); and C. psoraleae, known from Myanmar on Psoralea corylifolia, can easily be distinguished from C. antarcticum by its smooth and wider conidia, 3.5–7 μm, and wider conidiogenous loci and conidial hila, 1–3 μm diam (Ellis 1972, Schubert 2005).
Cladosporium bruhnei

Ascomata pseudothecial, black, superficial, situated on a small stroma, globose, up to 250 µm diam; ostioles periphysate, with apical periphysoids present; wall consisting of 3–6 layers of reddish brown textura angularis. Asci fasciculate, bitunicate, subsessile, ovoid to broadly ellipsoidal, straight to slightly curved, 8-spored, 65–90 × 16–25 µm; with pseudoparenchymatal cells of the hamathecium persistent. Ascospores tri- to multiseriate, overlapping, hyaline, with irregular lumina, thick-walled, straight to slightly curved, fusoid-ellipsoidal with obtuse basal end, and acutely rounded apical end, widest near the middle of the apical cell, medianly 1-septate, not to slightly constricted at the septum, (20–)25–27(–30) × (5.5–)6–7 µm.

Mycelium superficial, hyphae branched, 1.5–8 µm wide, pluriseptate, broader hyphae usually slightly constricted at the septa and somewhat swollen, hyaline to subhyaline, almost smooth to somewhat verruculose or irregularly rough-walled, sometimes appearing to have a slime coat, walls unthickened. Conidiophores macronematous, sometimes also micronematous, arising as lateral or terminal branches from plagiotropous or ascending hyphae, erect, straight to more or less flexuous, sometimes geniculate, nodulose, usually with small head-like swellings, sometimes also with intercalary nodules, sometimes swellings protruding and elongated to one side, unbranched, occasionally branched, (7–)20–330 µm, sometimes even longer, (2–)3–5 µm wide, swellings (4–)5–8 µm wide, pluriseptate, not constricted at the septa, septa sometimes not very conspicuous, subhyaline to pale brown or pale olivaceous, smooth or somewhat verruculose, walls unthickened or almost so, more thickened with age. Conidiogenous cells integrated, usually terminal, cylindrical with a terminal head-like swelling, sometimes with a second swelling, 15–40 µm long, proliferation sympodial, with few conidigenous loci confined to swellings, up to five per swelling, loci protuberant, conspicuous, 1–2 µm diam, thickened and darkened-refractive. Conidia catenate, formed in branched chains, straight to slightly curved, small terminal conidia subglobose, oval to ovoid or somewhat limoniform, 4–9 × 2.5–3.5 µm [av. ± SD, 6.5 (± 1.5) × 3.1 (± 0.5) µm], aseptate; secondary ramoconidia and occasionally formed ramoconidia ellipsoid to subcylindrical or cylindrical, 10–24(–31) × 3–5(–7) µm [av. ± SD, 16.1 (± 4.1) × 4.1 (± 0.8) µm], rarely up to 40 µm long, 0–1–3-septate, very rarely 5-septate, subhyaline to pale brown or pale olivaceous, minutely verruculose to verrucose (mostly granulate with some muricate projections under SEM), walls unthickened or almost so, apex rounded or slightly attenuated towards apex and base, hila protuberant, conspicuous, 1–2 µm wide, up to 1 µm high, thickened and darkened-refractive; microcyclic conidiogenesis occurring.

Fig. 9. Cladosporium bruhnei (CPC 12211). Macro- and micronematous conidiophores and conidia. Scale bar = 10 µm. K. Schubert del.
Cultural characteristics: Colonies on PDA reaching 22–32 mm diam after 14 d at 25 ºC, olivaceous-grey to iron-grey, sometimes whitish, smoke-grey to pale olivaceous due to abundant aerial mycelium covering almost the whole colony, with age collapsing becoming olivaceous-grey, occasionally zonate, velvety to floccose, margin narrow, entire edge, white, glabrous to somewhat feathery, aerial mycelium sparse to abundant, white, fluffy, growth regular, flat to low convex, without prominent exudates, sporulating. Colonies on MEA reaching 21–32 mm diam after 14 d at 25 ºC, grey-olivaceous, olivaceous-grey to dull green or iron-grey, sometimes whitish to pale smoke-grey due to abundant aerial mycelium, olivaceous-grey to iron-grey reverse, velvety, margin narrow, entire edge to slightly undulate, white, radially furrowed, glabrous to slightly feathery, aerial mycelium sparse to abundant, mainly in the centre, white, fluffy, growth convex to raised, radially furrowed, distinctly wrinkled in the colony centre, without prominent exudates, sporulating. Colonies on OA reaching 20–32 mm diam after 14 d at 25 ºC, smoke-grey, grey-olivaceous to olivaceous-grey, greenish black or iron-grey reverse, margin narrow, entire edge, colourless to white, glabrous, aerial mycelium sparse to abundant, dark smoke-grey, diffuse, high, later collapsed, felty, growth flat, without prominent exudates, sporulation profuse.

Specimens examined: Sine loco et dato, CBS 118.54 = ATCC 11290 = IMI 049638. Australia, N.S.W., Barrington Tops National Park, isolated from leaves of Eucalyptus stellulata (Myrtaceae), 3 Jan. 2006; B. Summerell, CPC 12921.

Substrate and distribution: Living and decaying plant material, man, air, hypersaline and industrial water; widespread.

Notes: Cladosporium bruhnei proved to be an additional component of the herbarum complex. The species resembles C. herbarum s. str. as already stated by Linder (1947), but possesses consistently narrower conidia, usually 2.5–5 µm wide, and the conidiophores often form only a single apical swelling. The species was described by Bruhne (l.c.) as Hormodendrum hordei from Germany but type material could not be located. Linder (1947) examined No. 1481a-5 (Canada, N. Quebec, Sugluk, on Elymus arenarius var. villosus, 31 Jul. 1936, E. Meyer), presumably in the National Museum, and stated that this specimen agreed well with the description and illustration given by Bruhne (l.c.). Although the species occurs on numerous substrates and is widely distributed, it has not yet been recognised as a distinct species since it has probably been interpreted as a narrow variant of C. herbarum.

Based on morphology and DNA sequence data, the CBS strain CBS 177.71 chosen by Prasil & de Hoog (1988) as representative living strain of C. herbarum, rather clusters together with isolates of C. bruhe. The strain CBS 813.71 is an albino mutant of the latter species as it does not appear to contain colour pigment. Furthermore, all isolates from humans treated until now as C. herbarum proved to be conspecific with the narrow-spored C. bruhnei.

Although Davidiella tassiana (ascospores 17–25 × 6–8.5 µm, RO) was treated as synonymous to D. allicina (ascospores 20–27 × 6–7 µm, UPS) in Aptroot (2006), they differ in apical ascospore taper, with ascospores of D. allicina being acutely rounded, while those of D. tassiana are obtusely rounded. The same ascospore taper was also observed in the teleomorph of C. bruhe, and thus the name D. allicina is herewith linked to C. bruhe, which is distinct from C. herbarum, having D. tassiana as teleomorph.

Etymology: Refers to its morphological similarity to Cladosporium herbarum.

Differt a Cladosporio herbaro conidiis polymorphis, 3–33 × (2–)3–6(–7) µm, postremo latioribus, (3.5–)5–9(–11) µm, fuscis et crassitunicatis; et a Cladosporio macrocarpo conidiophoris leniter angustioribus, 3–5 µm latis, nodulis angustioribus, 5–8 µm latis.

Mycelium branched, (1–)2–8 µm wide, septate, often with small swellings and constrictions, subhyaline to pale brown or pale olivaceous-brown, smooth or almost so to somewhat verruculose, walls unthickened or almost so. Conidiophores macronematous and micronematous, arising lateral from plagiotropous hyphae or terminally from ascending hyphae. Macronematous conidiophores erect, straight to slightly flexuous, often geniculate, nodulose, with unilaterial or multilateral swellings, often numerous swellings in short succession giving them a gnarled appearance, often forming somewhat protruding or prolonged lateral swellings or a branch-
like prolongation below the terminal swelling (due to sympodial proliferation), unbranched or sometimes branched, 30–230 µm long or even longer, 3–5 µm wide, swellings 5–8 µm wide, septic, not constricted at septa, pale to medium olivaceous-brown, smooth or almost so, walls slightly thickened. *Conidiogenous cells* integrated, terminal or intercalary, cylindrical, usually nodulose to nodose forming distinct swellings, sometimes geniculate, 15–55 µm long, with numerous conidiogenous loci usually confined to swellings or situated on small lateral shoulders, sometimes on the top of short peg-like prolongations or denticles, loci protuberant, 1–2 µm diam, thickened and darkened-refractive. *Micronematous conidiophores* much shorter, narrower, paler, neither nodulose nor geniculate, arising laterally from plagiotropous hyphae, often only as short lateral denticles or branchlets of hyphae, erect, straight, conical to cylindrical, unbranched, 3–65 × 2–3 µm, mostly asceptate, sometimes up to five septa, subhyaline, smooth, walls unthickened. *Conidiogenous cells* integrated, terminal or conidiophores reduced to conidiogenous cells, conidiogenous loci solitary or sometimes as sympodial clusters of pronounced denticles, protuberant, 1–1.5 µm diam, thickened and somewhat darkened-refractive. *Conidia* polymorphous, two main morphological types recognisable, formed by the two different types of conidiophores, conidia formed by macronematous conidiophores catenate, in branched chains, straight to slightly curved, subglobose, obovoid, limoniform, ellipsoidal to cylindrical, 3–33 × (2–)3–6–7 µm [av. ± SD, 14.5 (± 7.9) × 5.2 (± 1.2) µm], 0–2–3-septate, sometimes slightly constricted at septa, septa median or somewhat in the lower half, pale to medium olivaceous-brown, verruculose to verrucose (granulate under SEM), walls slightly thickened, with up to three rarely four distal scars, with age becoming medium or even dark brown (chocolate brown), wider and more thick-walled, 5.5–33 × (3.5–)5–9–11 µm [av. ± SD, 14.4 (± 6.9) × 7.2 (± 1.9) µm], walls up to 1 µm thick, hila protuberant, 0.8–2–2.5 µm diam, thickened and darkened-refractive; microcyclic conidiogenesis occurring. *Conidia* formed by micronematous conidiophores paler and narrower, mostly formed in unbranched chains, sometimes in branched chains with up to three distal hila, slightly curved, limoniform, narrowly fusiform, almost filiform to subcylindrical, 10–26–35 × 2–3.5 µm [av. ± SD, 15.6 (± 6.2) × 2.9 (± 0.5) µm], 0–1–3-septate, subhyaline to pale brown, almost smooth to minutely verruculose, walls unthickened, hila protuberant, 1–1.5 µm diam, thickened and somewhat darkened-refractive.

![Fig. 13. Cladosporium herbaroides (CPC 12052). Macro- and micronematous conidiophores and conidia. Scale bar = 10 µm. K. Schubert del.](image-url)
**Fig. 14.** Cladosporium herbaroides (CPC 12052). A–D. Macronematous conidiophores. C. Conidial chain. E. Micronematous conidiophore. F. Microcyclic conidiogenesis. G. Conidia formed by micronematous conidiophores. Scale bars = 10 μm.

**Cultural characteristics:** Colonies on PDA attaining 23 mm diam after 14 d at 25 ºC, grey-olivaceous to olivaceous, olivaceous-grey reverse, velvety, margin regular, entire edge, narrow, feathery, aerial mycelium abundantly formed, loose, with age covering large parts of the colony, woolly, growth flat with somewhat elevated colony centre, folded, regular, deep into the agar, with few prominent exudates, sporulation profuse. Colonies on MEA attaining 24 mm diam after 14 d at 25 ºC, grey- to greenish olivaceous, olivaceous-grey or iron-grey reverse, velvety to powdery, margin narrow, colourless, entire edge, somewhat feathery, aerial mycelium pale olivaceous-grey, sparse, growth convex, radially furrowed, folded in the colony centre, without prominent exudates, sporulating. Colonies on OA attaining 23 mm diam after 14 d at 25 ºC, grey-olivaceous, margin more or less regular, entire edge, colourless, somewhat feathery, aerial mycelium whitish to smoke grey, at first sparse, later more abundantly formed, growth flat, without exudates, sporulation profuse.

**Substrate and distribution:** Hypersaline water; Israel.

**Notes:** Cladosporium herbaroides is morphologically similar to C. herbarum but differs in having somewhat longer conidia becoming wider, darker and even more thick-walled with age [at first conidia 3–33 × (2–)3–6(–7) μm, with age (3.5–)5–9(–11) μm wide]. Besides that, the species often produces a second conidial type formed on micronematous conidiophores, giving rise to unbranched conidial chains which are almost filiform, limoniform, narrowly fusiform to subcylindrical, much narrower and paler than the ones formed by macronematous conidiophores, 10–26(–35) × 2–3.5 μm. In C. herbarum, conidia formed by micronematous conidiophores do not occur as frequently as in C. herbaroides, and differ in being often clavate and somewhat wider, up to 4(–5) μm wide. Cladosporium macrocarpum is easily distinguishable by having somewhat wider conidiophores (3–)4–6 μm, with distinctly wider swellings, 5–10 μm wide, and the conidia are usually (3–)5–9(–10) μm wide.

For additional synonyms see Dugan et al. (2004), Schubert (2005).

Cladosporium herbaroides (CPC 12052). A. Overview of the growth characteristics of this fungus. Broad hyphae run over the surface of the agar, and possibly give rise to conidiophore branches. The conidiophores of this fungus can be rather long, resembling aerial hyphae. Clusters of conidia are clearly visible in this micrograph. B. The very wide surface hyphae can anastomose. C. Conidiophore with secondary ramoconidia and conidia. Note the variation in scar size. D. A very elaborate, complex conidiophore with different scars of variable size, one being more than 2 μm wide! E. Details of secondary ramoconidia and hila. Note the rather strong ornamentation in which smaller “particles” are between larger ones. F. Three conidia in a row. Note the scar formation in the chain and the reduction of the size of the cells throughout the spore-chain. The inset shows the resemblance of the scars on a conidiophore and on a secondary ramoconidium. Scale bars: A = 50 μm, B–C, F (inset) = 10 μm, D–E = 5 μm, F = 2 μm.

Ascomata pseudothecial, black, globose, erumpent to superficial, up to 200 μm diam, with 1(–3) short, periphysate ostiolar necks; wall consisting of 3–6 layers of medium red-brown textura angularis. Asci fasciculate, bitunicate, subsessile, obvoid to broadly ellipsoid, straight to slightly curved, 8-spored, 65–85 × 13–17 μm. Pseudoparaphyses absent in host material, but remnants observed when studied in culture, hyaline, septate, subcylindrical, anastomosing, 3–4 μm wide. Ascospores tri- to multiseriate, overlapping, hyaline, with irregular luminar inclusions, thick-walled, straight to slightly curved, fusoid-ellipsoidal with obtuse ends, widest near middle of apical cell, medianly 1-septate, not to slightly constricted at the septum, tapering towards both ends, but more prominently towards the lower end, (17–)20–23(–25) × (6–)7(–8) μm; becoming brown and verruculose in asci. Ascospores germinating after 24 h on MEA from both ends, with spore body becoming prominently constricted at the septum, but not distorting, up to 7 μm wide, hyaline to pale brown and appearing somewhat verruculose, enclosed in a mucoid sheath, with germ tubes being irregular, somewhat nodular.
Mycelium superficial, loosely branched, (0.5–)1–5 µm wide, septate, sometimes constricted at septa, hyaline, subhyaline to pale brown, smooth or almost so to verruculose or irregularly rough-walled, sometimes appearing irregular in outline due to small swellings and constrictions, walls unthickened to somewhat thickened, cell lumen appearing to be granular. Conidiophores both macro- and micronematous, arising laterally from plagiotropous hyphae or terminally from ascending hyphae. Macronematous conidiophores erect, straight to flexuous, somewhat geniculate-sinuous, nodulose to nodose with unilateral or multilateral swellings, with a single to numerous swellings in short succession giving the stalk a knobly/ gnarled appearance, unbranched or occasionally branched, up to three times, sometimes with a lateral branch-like proliferation below or at the apex, 10–320 × 3.5–5 µm, swellings 5–8(–9) µm wide, pluriseptate, septa sometimes constricted when formed after a node, pale to medium brown, older ones almost dark brown, paler towards the apex, smooth or minutely verruculose, walls thickened, sometimes even two-layered. Conidiogenous cells integrated, terminal or intercalary, nodulose to nodose, with a single or up to five swellings per cell, 10–24 µm long, proliferation sympodial, with several conidiogenous loci confined to swellings, mostly situated on small lateral shoulders, more or less protuberant, broadly truncate to slightly convex, 1.5–2.5 µm diam, thickened and somewhat darkened-refractive. Micronematous conidiophores hardly distinguishable from hyphae, sometimes only as short lateral outgrowth with a single apical scar, short, conical to almost filiform or narrowly cylindrical, non-nodulose, not geniculate, unbranched, 5–120 × 1.5–3(–4) µm, pluriseptate, not constricted at septa, cells usually very short, 5–15 µm long, subhyaline to pale brown, almost smooth to minutely verruculose or irregularly rough-walled, sometimes forming clavate conidia, up to 33 µm long, 0–2-septate. Conidiogenous cells integrated, terminal or conidiophores reduced to conidiogenous cells, narrowly cylindrical or filiform, with a single or two loci. Conidia catenate, in unbranched or loosely branched chains with branching mostly occurring in the lower part of the chain, straight to slightly curved, small terminal conidia without distal hilum obvoid, 4–10 × 3–5(–6) µm [av. ± SD, 7.8 (± 1.9) × 4.7 (± 0.9) µm], aseptate, intercalary conidia with a single or sometimes up to three distal hila limoniform, ellipsoid to subcylindrical, 6–16 × 4–6 µm [av. ± SD, 12.4 (± 1.6) × 5.3 (± 0.6) µm], 0–1-septate, secondary ramoconidia with up to four distal hila, ellipsoid to cylindrical-oblong, 12–25(–35) × (3)–5–7(–9) µm [av. ± SD, 18.8 (± 4.5) × 6.2 (± 0.9) µm], 0–(1–2)-septate, rarely with up to three septa, sometimes distinctly constricted at the septum, septum median or somewhat in the upper or lower half, pale greyish brown to brown to medium brown or greyish brown, minutely verruculose to verrucose, walls slightly to distinctly thickened, gulletuate to somewhat granular, usually only slightly attenuated towards apex and base, apex obtuse or slightly truncate, towards the base sometimes distinctly attenuated with hila situated on short stalk-like prolongations, hila slightly to distinctly protuberant, truncate to slightly convex, (0.8–)1–2.5(–3) µm wide, 0.5–1 µm high, somewhat thickened and darkened-refractive; microcyclic conidiogenesis occurring, conidia forming micro- and macronematous secondary conidiophores.

Cultural characteristics: Colonies on PDA reaching 19–37 mm diam after 14 d at 25 °C, grey-olivaceous to olivaceous-grey, whitish to smoke-grey or pale olivaceous-grey due to abundant aerial mycelium, velvety, reverse olivaceous-grey or iron-grey, margin almost colourless, regular, entire edge, glabrous to feathery, aerial mycelium abundant mainly in the colony centre, dense, fely, woolly, sometimes becoming somewhat reddish brown, fawn coloured, growth regular, flat to low convex with an elevated colony centre, sometimes forming few large prominent exudates, sporulation profuse. Colonies on MEA reaching 17–37 mm diam after 14 d at 25 °C, smoke-grey to pale olivaceous-grey towards margin, olivaceous-grey to iron-grey reverse, velvety, margin white, entire edge to slightly undulate, aerial mycelium abundant, dense, fluffy to fely, growth low convex or raised, radially furrowed, folded and wrinkled in the colony centre, without prominent exudates but sporulating. Colonies on OA reaching 12–28 mm diam after 14 d at 25 °C, olivaceous-grey to iron-grey, due to abundant aerial mycelium pale olivaceous-grey, olivaceous-grey reverse, margin narrow, more or less undulate, white, aerial mycelium white, loose to dense, high, fluffy to fely, covering large parts of the colony, growth flat to low convex, without prominent exudates, sporulating.

Substrate and distribution: On fading and decaying plant material, on living leaves (phylloplane fungus), as secondary invader, as an endophyte, isolated from air, soil, foodstuffs, paints, textiles and numerous other materials; cosmopolitan.

Notes: De Vries (1952) incorrectly selected a specimen of Link’s herbarium at herb. B as lectotype. Prasil & de Hoog (1988) discussed this typification and designated one of Persoon’s original specimens as lectotype in which C. herbarum could be recognised. The latter material, which is in poor condition, could be re-examined within the course of these investigations and showed conidia agreeing with the current species concept of C. herbarum being (6–)9.5–14.5(–21) × (5–)6–7(–8) μm. Since the identity of the strain CBS 177.71 chosen by Prasil & de Hoog (1988) as representative living strain of C. herbarum could not be corroborated, an epitype with a living ex-epitype culture is designated. The holotype specimen of D. tassiana (RO) is morphologically similar to that observed on the epitype of C. herbarum, having ascospores which are (17–)21–23(–25) × (6–)7–8(–8.5) μm, turning brown and verruculose in asci with age. However, no hamathelial remnants were observed in ascomata in vivo.

The connection to the teleomorph D. tassiana could be confirmed, which is in agreement with the findings of von Arx (1950) and Barr (1958). Ascospore isolates formed the typical C. herbarum anamorph in culture, and these anamorph cultures developed some immature fruiting bodies within the agar. When inoculated onto water agar plates with nettle stems, numerous ascomata with viable ascospores were formed in culture.

For additional synonyms see Dugan et al. (2004).

Mycelium branched, 2–8 µm wide, septate, not constricted at the septa, hyaline to pale brown, smooth, walls slightly thickened, sometimes guttulate. Conidiophores very long, usually terminally arising from ascending hyphae, erect to subdecumbent, slightly to distinctly flexuous, geniculate-sinuous, usually several times, subnodulose due to geniculate, sympodial proliferation forming swollen lateral shoulders, unbranched, rarely branched, up to 720 µm long, 6–11 µm wide, swellings 8–11(–14) µm wide, pluriseptate, often very regularly septate, not constricted at the septa, pale to medium olivaceous-brown, somewhat paler towards the apex, smooth to minutely verruculose, walls only slightly thickened. Conidiogenous cells integrated, terminal as well as intercalary, cylindrical-oblong, 15–55 µm long, proliferation percurrent to sympodial, usually with a single geniculation forming laterally swollen shoulders often below a septum, conidiogenous loci confined to swellings, usually one locus per swelling, rarely two, protuberant, (2–)2.5–4 µm diam, somewhat thickened and darkened-refractive. Conidia solitary, sometimes in short, unbranched chains, straight to curved, young conidia pyriform to subcylindrical, connection between conidiophore and conidium being rather broad, subhyaline to pale olivaceous-brown, walls slightly thickened, then enlarging and becoming more thick-walled, cylindrical-oblong, soleiform with age, both ends rounded, usually with a slightly to distinctly bulbous base, visible from a very early stage, but broadest part often towards the apex, not at the base, (18–)30–75(–87) × (7–)10–16(–18) µm [av. ± SD, 53.3 (± 17.8) × 12.6 (± 2.2) µm], (0–)2–6(–7)-septate, usually not constricted at the septa, rarely slightly constricted, septa often becoming sinuous with age, pale to medium olivaceous-brown, sometimes darker, verrucose to echinulate, walls thickened, especially in older conidia, up to 1 µm thick, hila protuberant, often stalk-like or conically prolonged, up to 2 µm long, (2–)2.5–3.5(–4) µm diam, with age becoming more sessile, sometimes just visible as a thickened plate just below the outer wall layer, especially in distal scars of branched conidia, periclinal rim often distinctly visible, hila somewhat thickened and darkened-refractive; microcyclic conidiogenesis not observed.
Cladosporium herbarum
SpecieS coMplex

Fig. 19. Cladosporium herbarum (CPC 11600). A. Overview of hyphal growth and conidiophore formation of a colony on SNA. Conidiophores are often formed on very wide (approx. 10 μm), septate hyphae that often grow near the agar surface. B. A more detailed view on colony organisation reveals the ornamented conidia. Note the septum near the conidiophore (arrow). C. Detail of spore ornamentation and hila on a secondary ramoconidium (arrow). Ornamentation is visible during early stages of spore formation (arrow). D. Structure of the conidiophore, illustrating the complex morphology of the spore-forming apparatus. In addition, secondary ramoconidia, conidia, and a hilum on the conidium are visible. E. Complex structure of the spore-forming apparatus. F. Details of secondary ramoconidia with complex scar-pattern on the right cell. G. Details of a secondary ramoconidium giving rise to conidia. Note the lack of ornamentation at the location of spore formation. Scale bars: A = 50 μm, B, F = 10 μm, C–E, G = 5 μm.

Cultural characteristics: Colonies on PDA reaching 19–23 mm diam after 14 d at 25 °C, pale greenish olivaceous, smoke-grey to olivaceous-grey due to abundant aerial mycelium, greenish olivaceous to olivaceous reverse, margin broad, regular, entire edge to slightly undulate, feathery, aerial mycelium abundantly formed, felty, fluffy, covering large parts of the colony, mainly in the central parts, high, growth low convex with a somewhat raised colony centre. Colonies on MEA reaching 9–23 mm diam after 14 d at 25 °C, pale olivaceous-grey to olivaceous-grey, olivaceous-grey reverse, felty, margin slightly undulate, white, aerial mycelium abundant, loose, diffuse, high, growth low convex, radially furrowed, slightly folded. Colonies on OA reaching 10–19 mm diam after 14 d at 25 °C, olivaceous, margin broad, undulate, white, aerial mycelium white, very high, loose, diffuse, hairy, growth flat, due to the mycelium low convex, without prominent exudates and sporulating on all media.

Fig. 20. Cladosporium iridis (CBS 138.40). Conidiophores and conidia. Scale bar = 10 µm. K. Schubert del.

Fig. 21. Cladosporium iridis (teleomorph Davidiella macrospora) (CBS 138.40). A–C. Conidiophores with conidia. D. Conidium. Scale bar = 10 µm.
Substrates and distribution: Leaf spot and blotch of Iris spp. including I. crocea, I. florentina, I. foetidissima, I. germanica, I. gueldenstaedtiana, I. kamaonensis, I. palida, I. plicata (= I. swertii Hort.), I. pseudacorus, I. pumila, I. spuria ssp. halophila, and other species, also on Belacamanda chinensis (= Gemmingia chinensis), Hemerocallis fulva, Gladiolus gandavensis; Africa (Algeria, Morocco, South Africa, Zambia, Zimbabwe), Asia (Armenia, Azerbaijan, China, Georgia, India, Iran, Israel, Japan, Kazakhstan, Kirgizstan, Korea, Russia, Turkey, Turkmenistan, Uzbekistan), Australasia (Australia, New Zealand), Europe (Austria, Belgium, Belorussia, Cyprus, Czech Republic, Denmark, Estonia, France, Germany, Great Britain, Greece, Italy, Latvia, Lithuania, Malta, Moldavia, Montenegro, Netherlands, Norway, Poland, Romania, Russia, Serbia, Spain, Sweden, Ukraine), North America (Canada, U.S.A.), Central & South America (Argentina, Chile, Jamaica, Panama, Uruguay).

Notes: The description of the morphological parameters in culture is based on the isolate sporulating on PDA, since sporulation on SNA was not observed. The conidiophores and conidia in vivo are usually wider than in culture (conidiophores (6–)9–15(–17) µm wide, conidia (11–)15–23(–28) µm).

Fig. 22. Cladosporium macrocarpum (CBS 299.67). Macro- and micromenatous conidiophores and conidia. Scale bar = 10 µm. K. Schubert del.

**Cladosporium macrocarpum** Preuss, in Sturm, Deutsch. Fl. 3(26): 27. 1848. Figs 22–25.

For additional synonyms see Dugan et al. (2004), Schubert (2005).

Teleomorph: **Davidiella macrocarpa** Crous, K. Schub. & U. Braun, sp. nov. MycoBank MB504582.

Davidiellae tassianae similis, sed pseudoparaphysibus prominentibus et ascosporis maiores, (22–)23–26(±28) × (6–)6.5–7(–8) µm.

**Ascomata** superficialia on a small stroma, black, up to 200 µm diam, globose, separate, but developing with 1–3 necks with age; ostiolar consisting of pale brown to subhyaline cells, periphysate, with periphysoids growing into the cavity; wall consisting of 3–6 layers of medium brown textura angularis. **Pseudoparaphyses** present, hyaline, subcylindrical, septate, anastomosing, 3–4 µm diam; hamathecial cells persistent in cavity. Asci fasciculate, bitunicate, subsessile, broadly ellipsoid with a long tapered stalk, straight to curved, 8-spored, 70–110 × 15–20 µm. **Ascospores** tri- to multiseriate, overlapping, hyaline, guttulate, irregular lumina.
rarely observed, thick-walled, straight to slightly curved, fusoid-ellipsoidal with obtuse ends, widest in the middle of the apical cell, medianly 1-septate, not to slightly constricted at the septum, tapering towards both ends, but more prominently towards lower end, (22–)23–26–28(–28) × (6–)6.5–7(–8) µm; mucoid sheath rarely observed, mostly absent.

*Mycelium* unbranched or loosely branched, 1–4.5(–5) µm wide, septate, sometimes slightly constricted at septa, hyaline to pale brown, smooth to minutely verruculose, walls unthickened or slightly thickened. *Conidiophores* micronematous and macronematous, solitary, arising terminally from plagiotropous hyphae or terminally from ascending hyphae. *Macronematous conidiophores* erect, straight to somewhat flexuous, cylindrical-oblong, nodulose to nodose, with a single apical or usually several swellings either somewhat distinct from each other or often in short succession giving conidiophores a knotty appearance, swellings sometimes laterally elongated or formed at the top of a branch-like outgrowth below the apical swelling, sometimes distinctly geniculate, unbranched, sometimes branched, 12–260 × (3–)4–6 µm, swellings 5–10 µm wide, pluriseptate, sometimes slightly constricted at septa, pale to medium brown or olivaceous-brown, somewhat paler at apices.
smooth to minutely verruculose or verruculose, walls somewhat thickened, sometimes even two-layered. Conidiogenous cells integrated, terminal or intercalary, cylindrical, nodulose with lateral shoulders or nodose with swellings round about the stalk, with conidiogenous loci confined to swellings, 12–37 µm long, with up to 12 loci per cell, usually with up to six, loci conspicuous, protuberant, (1–)1.5–2 µm diam, somewhat thickened and darkened-refractive. Micronematous conidiophores almost indistinguishable from hyphae, straight, narrowly filiform, non-nodulose or with a single or few swellings, mostly with small head-like swollen apices, usually
Colonies on PDA reaching 30–43 mm in diam after 14 d at 25 ºC, dark dull green to olivaceous-grey, olivaceous-grey, dark olivaceous- to iron-grey reverse, pulvinate, velvety, sometimes somewhat zonate, paler zones towards the margin, margin regular, entire edge, almost colourless to white, glabrous to feathery, aerial mycelium sparse to more abundant in the colony centre or covering large areas of the colony, hairy, fluffy or felty, white to smoke-grey, sometimes becoming reddish, livid red to vinaceous, growth flat, regular, sometimes forming few prominent exudates, exudates sometimes slightly reddish, sporulation profuse with two kinds of conidiophores, low and high. Colonies on MEA reaching 31–50 mm in diam after 14 d at 25 ºC, grey-olivaceous to olivaceous-grey or iron-grey, sometimes pale olivaceous-grey to whitish due to abundant aerial mycelium, olivaceous-grey or iron-grey reverse, velvety or powdery, margin narrow, entire edge, colourless to white, glabrous, aerial mycelium sparse to abundant, hairy or felty, growth regular, flat to low convex, radially furrowed, without prominent exudates, sporulation profuse. Colonies on OA reaching 29–40 mm in diam after 14 d at 25 ºC, grey-olivaceous, olivaceous-grey to dark smoke-grey, olivaceous-black or iron grey reverse, margin entire edge, narrow, colourless or white, glabrous, aerial mycelium sparse, mainly in the colony centre, felty, white to smoke-grey or grey-olivaceous, felty, growth flat, regular, without exudates, sporulating.

**Cultural characteristics:** Colonies on PDA reaching 30–43 mm in diam after 14 d at 25 ºC, dark dull green to olivaceous-grey, olivaceous-grey, dark olivaceous- to iron-grey reverse, pulvinate, velvety, sometimes somewhat zonate, paler zones towards the margin, margin regular, entire edge, almost colourless to white, glabrous to feathery, aerial mycelium sparse to more abundant in the colony centre or covering large areas of the colony, hairy, fluffy or felty, whitish to smoke-grey, sometimes becoming reddish, livid red to vinaceous, growth flat, regular, sometimes forming few prominent exudates, exudates sometimes slightly reddish, sporulation profuse with two kinds of conidiophores, low and high. Colonies on MEA reaching 31–50 mm in diam after 14 d at 25 ºC, grey-olivaceous to olivaceous-grey or iron-grey, sometimes pale olivaceous-grey to whitish due to abundant aerial mycelium, olivaceous-grey or iron-grey reverse, velvety or powdery, margin narrow, entire edge, colourless to white, glabrous, aerial mycelium sparse to abundant, hairy or felty, growth regular, flat to low convex, radially furrowed, without prominent exudates, sporulation profuse. Colonies on OA reaching 29–40 mm in diam after 14 d at 25 ºC, grey-olivaceous, olivaceous-grey to dark smoke-grey, olivaceous-black or iron grey reverse, margin entire edge, narrow, colourless or white, glabrous, aerial mycelium sparse, mainly in the colony centre, felty, white to smoke-grey or grey-olivaceous, felty, growth flat, regular, without exudates, sporulating.

**Specimens examined:** Sine loco et dat. L 910.255-723 = L-0115836, **lectotype designated here of Derrnamium graminii**. Sine loco, on dead stems of Brassica sp. (Brassicaceae), No. 601, L 910.255-716 = L-0115849, **holotype of D. herbarum var. (β)** Brassicae. Sine loco, on leaves of Iris (Iridaceae), Quercus (Fagaceae), Brassica etc., L 910.255-736 = L-0115871, **holotype of D. vulgare var. (β)** foliorum, isotype L 910.255-716 = L-0115872. Sine loco et dat. L 910.256-686 = L-0115852, **lectotype designated here for D. vulgare var. (β)** typarum. Isolated from "Mycotheca Italica no. 1396 from Saccoard's herbarum (Herb. Myc. P.A. Saccardo no. 419, PAD)." D. macrocarpa (CPC 12755). Ascus and ascospores. Scale bar = 10 µm. P.W. Crous del. only few micrometer long, 1.5–3 µm wide, aseptate or with only few septa, subhyaline, smooth or almost so, walls unthickened, with a single or only few conidiogenous loci, narrow, 0.8–1.2 µm diam, thickened and somewhat darkened-refractive. Conidia catenate, in branched chains, small terminal conidia subglobose, obvoid, oval, limoniform, 4–11 × (3–)4–6 µm [av. ± SD, 7.6 (± 1.9) × 5.0 (± 0.8) µm], aseptate, intercalary conidia broadly ovoid-ellipsoid, 10–17 × (4.5–)5–9 µm [av. ± SD, 12.7 (± 2.1) × 6.8 (± 0.8) µm], 0–1-septate; secondary ramoconidia broadly ellipsoid to subcylindrical, 14–25(–30) × (5–)6–9(–10) µm [av. ± SD, 19.4 (± 3.5) × 7.6 (± 1.0) µm], 0–2(–3)-septate, sometimes slightly constricted at the septa, septa somewhat sinuous with age, pale brown to medium olivaceous-brown or brown, sometimes even dark brown, verruculose to echinulate (muricate under SEM), walls thickened, up to 1 µm thick, mostly broadly rounded at apex and base, sometimes attenuated, sometimes guttulate by oil drops, with up to three apical hila, mostly 1–2, hila sessile (apparently somewhat immersed) to somewhat protuberant, 1–2(–2.5) µm diam, thickened and darkened-refractive; microcyclic conidiogenesis occurring with conidia forming secondary micro- and macroconidial conidiophores, conidia often germinating with long hyphae. Conidia formed by micronematous conidiophores usually smaller, narrower and paler, catenate, in short unbranched or branched chains, subglobose, obvoid to limoniform, ellipsoid or fusiform, 2.5–16 × 1.5–5 µm, 0(–1)-septate, few longer conidia subcylindrical to clavate, up to 37(–43) µm long, 0–2(–3)-septate, occasionally with up to four septa, sometimes slightly constricted at the septa, subhyaline to pale brown, almost smooth to minutely verruculose, walls unthickened, hila 0.8–1.2 µm diam, thickened and darkened-refractive.

**Substrate and distribution:** Decaying plant material, human, hypersaline water, water, widespread.

**Notes:** In the absence of Preuss’s type material (not preserved) de Vries (1952) “lectotypified” C. macrocarpum by a specimen in Saccardo’s herbarum (Herb. Myc. P.A. Saccardo no. 419, PAD). This material, subsequently distributed in Mycotheca Italica no. 1396, should correctly be regarded as neotype (David 1997). A single collection of Saccardo’s Mycotheca Italica no. 1396 from herb. HBG, which can be considered as isoneotype material,
was re-examined and proved to rather agree with the species concept of *C. herbarum* s. str. The conidia were formed in simple, rarely branched chains, 6–26 × (4–)5.5–8(–9) µm, 0–3-septate, almost smooth or minutely to densely verruculose or verrucose (Schubert 2005). However, since de Vries’ “lectotypification” was incorrect according to the code (ICBN, Art. 9.2, 9.17), a neotype is designated.

The delimitation of *C. macrocarpum* as a morphologically distinct species from *C. herbarum* has been controversially discussed by several authors (McKemy & Morgan-Jones 1991, Dugan & Robert 1994, Ho et al. 1999). Based on molecular as well morphological studies, it can be shown that *C. macrocarpum* is a well-defined species distinguishable from *C. herbarum* s. str. by forming conidiophores with wider nodes, 5–10 µm, wider and more frequently septate conidia [small terminal conidia 4–11 × (3–)4–6 µm versus 4–10 × 3–5(–6) µm in *C. herbarum*, intercalary conidia 10–17 × (4.5–)5–9 µm versus 6–16 × 4–6 µm in *C. herbarum*, secondary ramoconidia 14–25(–30) × (5–)6–9(–10) µm versus 12–25(–35) × (3–)5–7(–9) µm in *C. herbarum*] and by being connected to *Davidiella macrocarpa*. On natural substrates the conidiophores are usually somewhat wider than in culture, 4–8(–10) µm wide, and also the conidia can be somewhat wider, sometimes up to 13(–15) µm.

*Cladosporium graminum*, described by Persoon (1822), as well as *C. brunneum* and *C. gracile*, introduced by Corda (1837), are older synonyms of *C. macrocarpum* and, according to the code, would have priority. However, since *C. macrocarpum* is a well established, currently used name with numerous records in literature, a proposal to conserve the name against these older names is in preparation for formal publication in *Taxon*.

A characteristic difference between ascomata of *C. macrocarpum* in comparison to those of *C. herbarum*, are the smaller, globose pseudothecia, asci with longer stalks, prominence of pseudoparaphyses, and rather inconspicuous luminar ascospore inclusions.

≡ *Heterosporium ossifragi* (Rostr.) Lind, Dan. fung.: 531. 1913.
Fig. 27. Cladosporium ossifragi (CBS 842.91). A. Macronematous conidiophore. B. Micronematous conidiophore. C–D. Conidia. E. Conidia and microcyclic conidiogenesis. Scale bars = 10 µm.

Fig. 28. Cladosporium ossifragi (CBS 842.91). A. Survey on different secondary ramoconidia and conidia. B. Details of conidia and hila. Note the very pronounced ornamentation and the absence of ornamentation near the site of spore formation. C. Detail of the end of a secondary ramoconidium with pronounced hila. D. Formation of a new conidium. Note the broad scar behind it (> 1 μm). E. Formation of a new conidium from a smooth-walled stalk. F. Hila on a secondary ramoconidium. This micrograph is from the sample before coating with gold-palladium and shows similar features as the sample after sputter coating. Scale bars: A = 10 µm, B–D, F = 2 µm, E = 5 µm.
Mycelium abundantly formed, twisted, often somewhat aggregated, forming ropes, branched, 1–5 µm wide, septate, often irregularly swollen and constricted, hyaline or subhyaline to pale brown, smooth, walls unthickened or only slightly thickened. Conidiophores macroconidial and microconidial, arising from plagiotropic hyphae, terminally or laterally, erect to subdecumbent, more or less straight to flexuous, cylindrical, sometimes geniculate, subnudolus with loci often situated on small lateral shoulders, unbranched, sometimes branched, often very long, up to 350 µm long, 3–4–5(–5) µm wide, pluriseptate, shorter ones aseptate, not constricted at septa, pale to pale medium brown, paler towards apices, sometimes subhyaline, smooth to minutely verruculose, especially towards apices, walls somewhat thickened, up to 0.5 µm, sometimes appearing two-layered. Conidiogenous cells integrated, terminal as well as intercalary, cylindrical, sometimes geniculate, subnudolus, 5–31 µm long, proliferation symphodial, with few loci (1–3) per cell, loci usually confined to small lateral shoulders, protuberant, conspicuous, short cylindrical, 1–2 µm wide, up to 1 µm high, somewhat thickened, darkened-refractive. Conidia catenate, in short, unbranched or branched chains, straight, small terminal and intercalary conidia subglobose, often obtuse to ellipsoid, 4–15 × 3–5 µm [av. ± SD, 9.3 (± 3.7) × 4.0 (± 0.7) µm], 0–1-septate, not constricted at the septa, pale brown, hila 0.8–1 µm diam, secondary ramosconidia cylindrical, sometimes ellipsoid or subfusciform, 16–36–(40) × (4)–5–8 µm [av. ± SD, 26.6 (± 7.4) × 6.0 (± 1.2) µm], (0)–1–3–(4)-septate [in vivo wider, (6)–7–9–(11) µm, and with up to five, rarely seven septa], not constricted at the septa, septa sometimes slightly sinuous, pale brown to pale medium brown, densely verruculose, verrucose to echinulate (densely muricate under SEM), walls unthickened to somewhat thickened, rounded or somewhat attenuated at apex and base, hila protuberant, conspicuous, sometimes situated on short, small prolongations, 1–2.5 µm diam, somewhat thickened and darkened-refractive; microcyclic conidiogenesis occasionally occurring.

Cultural characteristics: Colonies on PDA reaching 53 mm diam after 14 d at 25 °C, greenish olivaceous, grey-olivaceous to olivaceous-grey or iron-grey, appearing somewhat zonate, dull green to olivaceous-black reverse, margin colourless, regular, entire edge, aerial mycelium abundantly formed, covering at first the colony centre later most of the surface, dense, high, growth flat with elevated colony centre, somewhat folded. Colonies on MEA reaching 54 mm diam after 14 d at 25 °C, pale olivaceous-grey to olivaceous-grey in the centre, iron-grey reverse, velvety, margin colourless to white, entire edge, radially furrowed, aerial mycelium abundantly formed, fluffy to floet, growth flat with somewhat raised, folded colony centre. Colonies on OA attaining 52 mm diam after 14 d at 25 °C, olivaceous-grey to iron-grey, iron-grey to greenish black reverse, margin white, entire edge, aerial mycelium diffuse, loose, growth flat, prominent exudes absent, sporulation profuse on all media.

Substrate and distribution: Causing leaf spots on Narthecium ossifragum; Europe (Austria, Denmark, Germany, Great Britain, Ireland, Norway).

Notes: Type material of Naplicodium ossifragi is not preserved in Rostrup’s herbarium (on Narthecium ossifragum, Faeroe Islands, Viderø, Viderejde and Österø, Svinøa, sine dato, leg. Ostenfeld & Harz). However, other authentic collections seen and examined by Rostrup are deposited at CP. Lind (1913) re-examined these samples, synonymised N. ossifragi with H. magnusianum and correctly introduced the combination H. ossifragi. Nevertheless, the correct oldest name for this fungus has been ignored by most authors. David (1997), who clearly stated that N. ossifragi is the earliest name for this species, preferred to use the name C. magnusianum because the typification of Rostrup’s name was still uncertain. Despite the lacking type material, there is no doubt about the correct identity of N. ossifragi since authentic material of this species, examined by and deposited in Rostrup’s herbarium (CP), is preserved. Therefore, there is no reason to reject the oldest valid name for this species. The original collection of C. magnusianum cited by Jaap (1902) (on leaves of Narthecium ossifragum, Denmark, Tänder, Rámé, peatbog by Twismark, Jul.–Aug. 1901, Jaap), but not designated as type, is not preserved (David 1997). It is neither deposited at B, HBG nor S. However, in the protologue Jaap (1902) also referred to material of this species found near Hamburg, which is, hence, syntype material available for lectotypification.

Etymology: Epithet derived from its similar morphology to Cladosporium iridis.

Differt a Cladosporio iridis conidiis 0–3-septatis, brevioribus et latioribus, 15–55 × (9–)11–19(–21) µm.

Mycelium sparingly branched, 2–7 µm wide, septate, not constricted at the septa, subhyaline to pale brown, smooth or almost so, walls somewhat thickened, guttulate or protoplasm appearing granular, sometimes enveloped by a slime coat. Conidiophores arising mostly terminally from ascending hyphae, sometimes also laterally from plagiotropic hyphae, erect, more or less straight, broadly cylindrical-oblong, once or several times slightly to distinctly geniculate-sinuous, forming more or less pronounced lateral shoulders, nodulose, unbranched, 100–320(–500) × 7–11 µm, swellings 10–14 µm wide, becoming narrower and paler towards the apex, septate, not constricted at the septa, septa mainly basal, apical cell often very long, pale to medium olivaceous-brown, subhyaline at the apex, smooth or almost so, sometimes minutely verruculose, walls usually distinctly thickened, sometimes even two-layered, up to 1–(2) µm thick, protoplasm granular, often clearly contrasting from the outer wall. Conidiogenous cells integrated, terminal and intercalary, cylindrical-oblong, slightly to distinctly geniculate-sinuous, nodulose with conidiogenous loci confined to swellings or lateral shoulders, 30–110 µm long, proliferation percurrent to sympodial, with a single or three, sometimes up to five geniculations per cell, usually only a single locus per swelling, protuberant, very prominent, short cylindrical, peg-like, clearly composed of a dome and surrounding rim, dome often higher than the pericinal rim, broad, somewhat paler than rim, conically narrowed, (2–)2.5–4 µm wide, up to 2 µm high, thickened and darkened-refractive.
Conidia solitary, sometimes in short unbranched chains of two or three, straight to slightly curved, young conidia small, 0–1-septate, broadly ovoid to pyriform, 15–26 × (9–)11–16(–18) µm [av. ± SD, 19.2 (± 4.3) × 14.2 (± 3) µm], first septum somewhat in the upper half, the upper cell is much smaller but gradually extending as the conidium matures, mature conidia 1–3-septate, broadly pyriform, cylindrical-oblung or soleiform, usually with a distinctly bulbous base, 30–55 × 12–19(–21) µm [av. ± SD, 41.5 (± 6.8) × 17.1 (± 2.1) µm], broadest part of conidia usually at the bulbous base, mostly attenuated towards the basal septum, septa becoming sinuous with age, pale to medium olivaceous-brown or brown, usually echinulate, sometimes coarsely verrucose, walls distinctly thickened, up to 2 µm thick, often appearing layered with a large lumen in the centre of the cell, broadly rounded to flattened at apex and base, hila often very prominent, often peg-like elongated, up to 3 µm long, with age becoming less prominent, visible as a thickened flat plate just below the outer echinulate wall layer, slightly raised towards the middle, 2–3.5 µm diam, thickened and darkened-refractive; microcyclic conidiogenesis not observed.

Cultural characteristics: Colonies on PDA attaining 6 mm diam after 14 d at 25 ºC, whitish, smoke-grey to pale olivaceous-grey due to abundant aerial mycelium, olivaceous-black reverse, margin narrow, white, more or less crenate, aerial mycelium zonate, fluffy, covering most of the colony, mainly in the colony centre, growth
convex to raised, deep into the agar, with age few large prominent exudates formed, sparingly sporulating. Colonies on MEA attaining 7 mm diam after 14 d at 25 ºC, olivaceous-grey, pale olivaceous-grey to pale rosy-buff due to abundant aerial mycelium covering almost the whole colony, iron-grey reverse, margin colourless or white, broad, regular, more or less glabrous, aerial mycelium fluffy, dense, high, growth convex to umbonate, sometimes with elevated colony centre, prominent exudates lacking, sporulation sparse. Colonies on OA attaining 8 mm diam after 14 d at 25 ºC, white, pale buff to pale olivaceous-grey in the centre, margin grey-olivaceous, olivaceous- to iron-grey reverse, margin entire edge or somewhat undulate, somewhat feathery, growth raised with a somewhat depressed centre forming an elevated outer rim, without prominent exudates, sporulation more abundant.

Substrate and distribution: On living leaves of Iris sp.; New Zealand.

Notes: Cladosporium pseudiridis closely resembles C. iridis, a common and widespread species causing leaf spots on numerous Iris spp. and a few additional hosts of the host family Iridaceae, but the latter species is easily distinguishable by having longer and narrower, more frequently septate conidia, (18–)30–75(–87) × (7–)10–16(–18) µm, (0–)2–6(–7)-septate.

It is unlikely that C. pseudiridis is of New Zealand origin since the genus Iris is not indigenous to New Zealand. All Iris species that are found in this country have been introduced, mainly for horticultural purposes. The species is, therefore, probably more common than indicated above. However, within the course of the recent monographic studies in the genus Cladosporium numerous herbarium specimens, mainly of European origin, have been examined and proved to be correctly identified agreeing with the species concept of C. iridis. Additional collections and cultures are necessary to determine its distribution.

Etymology: Refers to the morphological similarity with Cladosporium tenellum.

Differt a Cladosporio cladosporioide conidiophoris et conidiis leniter angustioribus, 2–4(–5) µm latis, conidiis 0–2(–3)-septatis, semper verruculosis; et a Cladosporio tenello locis conidiogenis non numerosis et non aggregatos ad apicem, conidiis longioribus et angustioribus, 2.5–35 × 2–4(–5) µm, 0–3-septatis.

Mycelium unbranched or only sparingly branched, 1.5–4 µm wide, septate, without swellings and constrictions, hyaline or subhyaline, smooth, sometimes irregularly rough-walled, walls unthickened. Conidiophores solitary, macronematous and micromematous, arising as lateral branches of plagiotropous hyphae or terminally from ascending hyphae, erect, straight or slightly flexuous, cylindrical, neither geniculate nor nodulose, without head-like swollen apices or intercalary swellings, unbranched, sometimes
branched, branches often only as short lateral prolongations, mainly formed below a septum, 14–110 × 2–4 µm, septate, not constricted at the septa, subhyaline to pale olivaceous or brown, smooth to minutely verruculose, walls unthickened, sometimes guttulate. **Conidiogenous cells** integrated, terminal, sometimes also intercalary, cylindrical, not geniculate, non-nodulose, 10–28(–50) µm long, proliferation sympodial, with few conidiogenous loci, mostly 1–3, loci sometimes situated on small lateral prolongations, protuberant, 0.5–1.5(–2) µm diam, thickened and somewhat darkened-refractive. **Ramoconidia** formed, cylindrical-oblong, up to 47 µm long, 2–4 µm wide, 0–1-septate, rarely up to 4-septate, subhyaline to very pale olivaceous, smooth or almost so, with a broadly truncate base, without any dome and raised rim, 2–3 µm wide, not thickened but somewhat refractive. **Conidia** numerous, polymorphous, catenate in branched chains, straight, sometimes slightly curved, small terminal conidia numerous, globose, subglobose or ovoid, obvoid or limoniform, 2.5–7 × 2–4(–4.5) µm [av. ± SD, 5.1 (± 1.3) × 3.1 (± 0.6) µm], aseptate, without distal hilum or with a single apical scar, intercalary conidia ellipsoid to subcylindrical, 8–15 × 3–4(–4.5) µm [av. ± SD, 11.5 (± 2.4) × 3.6 (± 0.5) µm], 0–1-septate; secondary ramoconidia subcylindrical to cylindrical-oblong, 17–35 × 3–4(–5) µm [av. ± SD, 22.5 (± 5.6) × 3.7 (± 0.5) µm], 0–3-septate, not constricted at the septa, subhyaline to very pale olivaceous, minutely verruculose (granulate under SEM), walls unthickened or almost so, apex broadly rounded or slightly attenuated towards apex and base, sometimes guttulate, hila protuberant, conspicuous, 0.8–1.5(–2) µm diam, somewhat thickened and darkened-refractive; microcyclic conidiogenesis occurring.

**Cultural characteristics:** Colonies on PDA reaching 46–49 mm diam after 14 d at 25 ºC, olivaceous to grey-olivaceous due to abundant sporulation, appearing zonate in forming concentric zones, margin entire edge to slightly undulate, white, glabrous, aerial mycelium absent or sparse, growth flat with a somewhat folded and wrinkled colony centre, without prominent exudates, sporulation profuse. Colonies on MEA reaching 48–49 mm diam after 14 d at 25 ºC, grey-olivaceous to olivaceous-grey, velvety, olivaceous-grey to

Fig. 33. *Cladosporium ramotenellum* (CPC 12043). A. Survey of colony development showing a large bulbous “foot cell” that gives rise to conidiophores, which can be branched. B. Details of conidiophores showing secondary ramoconidia and conidia. The inset shows scar formation on a conidiophore. C. Conidiophore and several conidia. D. Details of ornamentation on conidia. Note the wide, but relatively low ornamentation units. E. A micrograph illustrating the organisation within a conidiophore. Scale bars A–D = 5 µm, E = 10 µm.
iron-grey reverse, margin entire edge to undulate, radially furrowed, colourless, glabrous to feathery, aerial mycelium sparse, diffuse, growth flat with slightly elevated colony centre, distinctly wrinkled, prominent exudates not formed, abundantly sporulating. Colonies on OA attaining 40 mm diam after 14 d at 25 ºC, grey-olivaceous, margin entire edge, colourless or white, glabrous, aerial mycelium absent or sparse, growth flat, without exudates, sporulation profuse.

Specimens examined: Slovenia, Ljubljana, isolated from an air conditioning system (bathroom), 2004, M. Butala, CBS 121627 = CPC 12047 = EXF-967; Sečovlje, isolated from hypersaline water from reverse ponds, salterns, 2005, P. Zalar, CBS-H 19862, holotype, isotype HAL 2026 F, culture ex-type CBS 121628 = CPC 12043 = EXF-454.

Substrate and distribution: Hypersaline water, air; Slovenia.

Notes: Cladosporium ramotenellum, which appears to be a saprobe in air and hypersaline water, morphologically resembles C. cladosporoides and C. tenellum K. Schub., Zalar, Crous & U. Braun, but is quite distinct from C. cladosporoides by having somewhat narrower conidiophores and conidia, 2–4(–5) µm wide, and 0–3-septate, always minutely verruculose conidia. Cladosporium tenellum, a newly introduced species (see below) isolated from hypersaline water and plant material, possesses conidiophores with numerous conidiogenous loci, usually crowded towards the apex forming sympodial clusters of pronounced scars, and shorter and somewhat wider, 0–1(–2)-septate conidia, 3–20(–28) × (2.5–)3–5(–6) µm. Besides these morphological differences, C. ramotenellum is faster growing in culture than C. tenellum.

Cladosporium arthrinioides Thüm. & Beltr. and C. hypophyllum Fuckel are also close to C. ramotenellum, but C. arthrinioides, known from Italy on leaves of Bougainvillea spectabilis, deviates in having shorter and wider, 0–1(–2)-septate, mostly smooth conidia (2–18 × 2–6.5 µm) which become larger and more frequently septate with age (up to 32 µm long and with up to four septa); and C. hypophyllum occurring in Europe on leaves of Ulmus minor differs in having often mildly to distinctly geniculate-sinuous, sometimes subnodulose conidiophores and shorter and somewhat wider, 0–1(–3)-septate conidia, 4–17(–19) × 2–5 µm, becoming distinctly swollen, darker, longer and wider with age, 5–7 µm, with the septa often being constricted (Schubert 2005).

**Etymology:** Refers to the usually distinctly sinuous conidiophores.

Diffrer a Cladosporio herbaro conidiophoris distincte sinuosis, conidiis solitariis vel breve catenatis, catenis non ramosis, echinulatis.

**Mycelium** sparingly branched, 1–7 µm wide, septate, not constricted at the septa, subhyaline to pale brown, smooth to minutely verruculose, walls unthickened or slightly thickened, sometimes with small swellings. **Conidiophores** arising laterally from plagiotropous hyphae or terminally from ascending hyphae, erect, more or less straight to flexuous, often once or several times slightly to distinctly geniculate-sinuous, sometimes even zigzag-like, nodulate with small to large lateral shoulders, shoulders somewhat distant from each other or in close succession giving them a knotty/gnarled appearance, unbranched or once branched, 25–260 × 5–7 µm, shoulders up to 10 µm wide, pluriseptate, septa sometimes in short succession, not constricted at the septa, pale brown to medium brown, smooth to minutely verruculose, walls thickened, often distinctly two-layered, up to 1 µm thick. **Conidiogenous cells** integrated, terminal or intercalary, often slightly to distinctly geniculate-sinuous, nodulate with small to large laterally swollen shoulders, 8–30 µm long, proliferation sympodial, with a single or up to three conidiogenous loci, usually confined to lateral shoulders, protuberant, often denticle-like or on the top of short cylindrical stalk-like prolongations, 1.2–2(–2.2) µm diam, mainly 2 µm, somewhat thickened and darkened-refractive, dome often slightly higher than the surrounding rim. **Conidia** solitary or in short unbranched chains with up to three conidia, straight, obvoid, oval, broadly ellipsoidal to subcylindrical or sometimes clavate (broader at the apex), 9–21 × (5–)6–8 µm [av. ± SD, 14.5 (± 2.5) × 6.6 (± 0.7) µm]. 0–1-septate, not constricted at the septa, septum more or less median, pale greyish brown, densely echinulate, spines up to 1 µm long, walls thickened, apex mostly broadly rounded or sometimes attenuated, towards the base mostly distinctly attenuated forming a peg-like prolongation, up to 2 µm long, hila protuberant, 1.2–2 µm diam, mainly 2 µm, somewhat thickened and darkened-refractive; microcyclic conidiogenesis not observed.

**Cultural characteristics:** Colonies on PDA attaining 20 mm diam after 14 d at 25 ºC, pale olivaceous-grey due to abundant aerial mycelium, olivaceous-grey towards margins, iron-grey to olivaceous-black reverse, margin regular, entire edge, aerial mycelium abundant, cottony, dense, high, growth regular, low convex, radially furrowed in the centre, growing deep into the agar, with age numerous small to large prominent exudates, sporulation sparse. Colonies on MEA attaining 16 mm diam after 14 d at 25 ºC, white to pale smoke-grey, fawn reverse, velvety, margin undulate, glabrous, aerial mycelium abundant, dense, high, fluffy, growth raised with elevated colony centre, laterally furrowed, without

---

prominent exudates. Colonies on OA attaining 18 mm diam after 14 d at 25 ºC, olivaceous, white to pale olivaceous-grey in the centre due to abundant aerial mycelium, olivaceous-grey reverse, margin white, entire edge, glabrous, aerial mycelium loose to dense, high, fluffy to felty, growth flat to low convex, regular, without prominent exudates, sporulating.

Substrate and distribution: On living leaves of Fuchsia excorticata; New Zealand.

Notes: This new species is well characterised by its slightly to distinctly geniculate-sinuous, often zigzag-like conidiophores and its conidia formed solitary or rarely in short unbranched chains and is therefore morphologically not comparable with any of the species described until now. Most Cladosporium species with conidia usually formed solitary or in short unbranched chains have previously been treated as species of the genus Heterosporium Klotzsch ex Cooke, now considered to be synonymous with Cladosporium. All of them, including the newly introduced C. arthropodi K. Schub. & C.F. Hill from New Zealand, which also belongs to this species complex (Braun et al. 2006), possess very large and wide, often pluriseptate conidia quite distinct from those of C. sinuosum (David 1997). Cladosporium alopecuri (Ellis & Everh.) U. Braun, known from the U.S.A. on Alopecurus geniculatus is also quite different by having larger and wider conidia, 20–40 × 7–13(–15) µm, and wider conidiogenous loci and conidial hila, 3.5–5 µm diam (Braun 2000).

Cladosporium herbarum is superficially similar but the conidiophores of the latter species are sometimes only slightly geniculate-sinuous but never zigzag-like and the verruculose conidia are frequently formed in unbranched or branched chains.

Cladosporium spinulosum Zalar, de Hoog & Gunde-Cimerman, Studies in Mycology 58: 180. 2007 – this volume. Fig. 36.

Note: This new species is described and illustrated in Zalar et al. (2007 – this volume).

**Etymology:** Refers to its nodulose conidiophores.

Differt a Cladosporio bruheii conidiophoris cum nodulis angustioribus, 3–6.5 µm latis, conidiis brevioribus, 4–17(–22) µm longis, spinulosis, cum spinulis ad 0.8 µm longis; et a Cladosporio spinuloso conidiophoris nodulosis, conidiis spinulosis, cum spinulis brevioribus, ad 0.8 longis, locis conidiogenis et hilis latioribus, (0.5–)1–2 µm latis.

**Mycelium** unbranched or occasionally branched, 1.5–3 µm wide, later more frequently branched and wider, up to 7 µm wide, septate, not constricted at the septa, hyaline or subhyaline, almost smooth to somewhat verruculose or irregularly rough-walled, walls unthickened. **Conidiophores** mainly macronematous, sometimes also micronematous, arising terminally from ascending hyphae or laterally from plagiotropous hyphae, erect or subdecumbent, straight or flexuous, sometimes bent, cylindrical, nodulose, usually with small head-like swellings, sometimes swellings also on a lower level or intercalary, occasionally geniculate, unbranched, occasionally branched, (5–)10–270 × (1.5–)2.5–4.5(–5.5) µm, swellings 3–6.5 µm wide, aseptate or with few septa, not constricted at the septa, pale brown, pale olivaceous-brown or somewhat reddish brown, smooth, usually verruculose or irregularly rough-walled and paler, subhyaline towards the base, walls thickened, sometimes appearing even two-layered, up to 1 µm thick. **Conidiogenous cells** integrated, usually terminal or conidiophores reduced to conidiogenous cells, cylindrical, nodulose, usually with small head-like swellings with loci confined to swellings, sometimes geniculate, 5–42 µm long, proliferation sympodial, with several loci, up to four situated at nodules or on lateral swellings, protuberant, conspicuous, denticulate, (0.8–)1–2 µm diam, thickened and darkened-refractive. **Conidia** catenate, in branched chains, more or less straight, numerous globose and subglobose conidia, ovoid, obovoid, broadly ellipsoid to cylindrical, 4–17(–22) × (2.5–)3.5–5.5(–7) µm [av. ± SD, 11.7 (± 4.6) × 4.5 (± 0.8) µm], 0–1(–2)-septate, not constricted at septa, pale brown or pale olivaceous-brown, ornamentation variable, mainly densely verruculose to echinulate (loosely muricate under SEM), spines up to 0.8 µm high, sometimes irregularly verrucose with few scattered tubercles.

Many of the hyphae have a collapsed appearance. B. Detail of colony with conidiophores, conidia and aerial hyphae that are partly collapsed. C. Detail of a conidiophore end and a secondary ramoconidium. Note the scars at the end of the conidiophore. D. Details of conidia and ornamentation. The ornamentation consists out of markedly defined units, which have a relatively large distance from each other. Note the hilum on the right conidium. E. Conidiophore with large scars and conidia. F. Different blastoconidia with very early stages of new spore formation in the middle of the picture. G. Pattern of spore development. Scale bars: A = 20 µm, B, E–G = 5 µm, C = 10 µm, D = 2 µm.
or irregularly echinulate, walls unthickened or slightly thickened, apex rounded or slightly attenuated towards apex and base, hila conspicuous, protuberant, denticulate, 0.5–2 µm diam, thickened and darkened-refractive; microcyclic conidiogenesis observed.

Cultural characteristics: Colonies on PDA attaining 29 mm diam after 14 d at 25 ºC, olivaceous-black to olivaceous-grey towards margin, margin regular, entire edge, narrow, colourless to white, glabrous to feathery, aerial mycelium formed, fluffy, mainly near margins, growth flat, somewhat folded in the colony centre, deep into the agar, few prominent exudates formed with age, sporulation profuse. Colonies on MEA attaining 25 mm diam after 14 d at 25 ºC, olivaceous-grey to olivaceous due to abundant sporulation in the colony centre, pale greenish grey towards margin, iron-grey reverse, velvety to powdery, margin crenate, narrow, white, glabrous, radially furrowed, aerial mycelium diffuse, growth convex with papillate surface, wrinkled colony centre, without prominent exudates, sporulation profuse. Colonies on OA attaining 26 mm diam after 14 d at 25 ºC, olivaceous, iron-grey to greenish black reverse, growth flat, deep into the agar, with a single exudate, abundantly sporulating.

Substrate and distribution: Hypersaline water; Slovenia.

Notes: Cladosporium subinflatum, an additional saprobic species isolated from hypersaline water, was at first identified as C. spinulosum, but proved to be both morphologically as well as phylogenetically distinct from the latter species in having somewhat wider [(1.5–)2.5–4.5(–5.5) µm], nodulose macronematous conidiophores with conidiogenous loci confined to swellings, wider conidiogenous loci and hila, (0.8–)1–2 µm, and spiny conidia with shorter spines than in C. spinulosum (up to 0.8 µm versus 0.5–1.3 µm long) (Zalar et al. 2007). With its narrow, nodulose macronematous conidiophores and catenate conidia, C. bruhnei is morphologically also similar but differs by having conidiophores with wider swellings, (4–)5–8 µm, and longer conidia 4–24(–31) µm, rarely up to 40 µm long which are minutely verruculose to verrucose but not spiny.

Fig. 40. Cladosporium subtilissimum (CBS 113754). Macro- and micronematous conidiophores and conidia. Scale bar = 10 µm. K. Schubert del.

Etymology: Refers to its narrow conidiophores and conidia.

Differt a Cladosporio cladosporioide conidiophoris et conidiis semper asperulatis ad verruculosis, conidiis 0–1(–2)-septatis.

Mycelium unbranched or sparingly branched, 1–5 µm wide, septate, without swellings and constrictions, hyaline to subhyaline or pale brown, smooth to minutely verruculose, walls unthickened or almost so, protoplasm somewhat guttulate or granular. Conidiophores macronematous and micronematous, arising laterally from plagiotropous hyphae or terminally from ascending hyphae, erect, straight to slightly flexuous, filiform to cylindrical-oblong, non-noduclose, sometimes geniculate towards the apex, unbranched or once branched, branches short to somewhat longer, usually formed below a septum, sometimes only short, denticle-like or conical, 25–140 × 2–4 µm, 0–4-septate, not constricted at the septa, subhyaline to pale brown, almost smooth, minutely verruculose to verruculose, sometimes irregularly rough-wall in the lower part, walls unthickened or slightly thickened, protoplasm guttulate or somewhat granular. Conidiogenous cells integrated, terminal or pleurogenous, sometimes also intercalary, filiform to narrowly cylindrical, non-nodulose, sometimes geniculate, 14–57 µm long, with usually sympodial clusters of pronounced conidiogenous loci at the apex or on a lower level, denticle-like or situated on short lateral prolongations, up to five loci, intercalary conidiogenous cells usually with a short denticle-like lateral outgrowth below a septum, protuberant, denticulate, somewhat truncate, 1.2–2 µm diam, thickened and darkened-refractive. Ramoconidia sometimes occurring, conidiogenous cells seceding at one of the upper septa of the conidiophore and behaving like conidia, filiform or cylindrical, 20–40(–55) µm long, 1.5–4 µm wide, 0–1-septate, concolorous with conidiophores, not attenuated towards apex and base, base broadly truncate, non-cladosporioid, without any dome and raised rim, 2–3.5 µm wide, neither thickened nor darkened, sometimes slightly refractive. Conidia catenate, in branched chains, up to 12 or even more in a chain, straight, small terminal conidia numerous, subglobose, narrowly ovoid, limoniform or fusiform, 4–9 × 2–3.5 µm [av. ± SD, 6.4 (± 1.5) × 2.8 (± 0.4) µm], with up to three distal scars, aseptate, hila (0.5–)0.8–1 µm diam, intercalary conidia narrowly ellipsoid, fusiform to subcylindrical, 9–18 × 3–4(–6) µm [av. ± SD, 13.0 (± 2.5) × 3.8 (± 0.3) µm], 0(–1)-septate, hila 1–1.2(–1.8) µm diam, with up to four distal scars, secondary ramoconidia ellipsoid, fusiform or subcylindrical, (13–)17–32(–37) × 3–5(–6) µm [av. ± SD, 21.4 (± 4.4) × 4.1 (± 0.5) µm], 0–1(–2)-septate, septum median or somewhat in the lower half, usually not constricted at the septa, with up to six distal hila crowded at the apex, hila (1.2–1.5)–2(–2.5) µm diam, apex often somewhat laterally enlarged or prolonged with hila crowded there, very pale or pale brown or olivaceous-brown, minutely verruculose to verruculose (granulate under SEM), walls unthickened or only slightly thickened, often slightly attenuated towards apex and base, protoplasm often guttulate or granular, hila protuberant, denticulate, 0.5(–)0.8–2(–2.2) µm diam, thickened and darkened-refractive; microcyclic conidiogenesis occasionally observed.

Cultural characteristics: Colonies on PDA attaining 24 mm diam after 14 d at 25 °C, grey-olivaceous to olivaceous, olivaceous-grey, iron-grey or olivaceous-black reverse, velvety, margin regular, entire edge, white or pale greenish olivaceous, glabrous to feathery, aerial mycelium sparse, only few areas with abundant
mycelium, diffuse, growth regular, flat or with a raised and wrinkled colony centre, radially furrowed, effuse, usually without prominent exudates, with age several exudates formed, sporulation profuse, colonies consisting of two kinds of conidiophores, short and a few longer ones. Colonies on MEA reaching 25 mm diam after 14 d at 25 °C, greenish olivaceous to grey-olivaceous in the centre, olivaceous-grey to iron-grey reverse, velvety, margin entire edge, crenate or umbonate, narrow, pale greenish olivaceous, sometimes radially furrowed, aerial mycelium absent or sparse, growth low convex with distinctly wrinkled colony centre, without prominent exudates, abundantly sporulating. Colonies on OA attaining 25 mm diam after 14 d at 25 °C, dark grey-olivaceous to olivaceous due to profuse sporulation, iron-grey reverse, sometimes releasing some olivaceous-buff pigments into the agar, velvety, margin regular, entire edge or crenate, narrow, colourless or white, glabrous or feathery, aerial mycelium sparse, growth flat with slightly raised colony centre, prominent exudates lacking, sporulation profuse.

Excluded strains within the subtilissimum complex: Argentina, isolated from Pinus ponderosa (Pinaceae), 2005, A. Greslebin, CPC 12484, CPC 12485; U.S.A., isolated from grape berry, F. Dugan, CBS 113741, CBS 113742; isolated from grape bud, F. Dugan, CBS 113744.

Substrate and distribution: Plant material and hypersaline water; Slovenia, U.S.A.

Notes: Cladosporium cladosporioides is morphologically comparable with the new species but deviates in having usually smooth conidiophores and conidia, with the conidia being mainly aseptate. C. subtilissimum is represented by three isolates of different origins.

**Cladosporium herbarum species complex**

Differs a Cladosporium cladosporioide conidiophoris et conidiis semper asperulatis, locis conidiogenis apicalibus, numerosis, hilis quoque numerosis, conidiophoris angustioribus, (1–)1.5–3.5(–4) µm latis; et a Cladosporio subtilissimo loci conidiogenis et hilis apicalibus, numerosis, angustioribus, saepe 1–1.5 µm latis, conidias minutis numerosis, saepe globose.

**Mycelium** sparingly branched, 1–3 µm wide, septate, septa often not very conspicuous, not constricted at the septa, sometimes slightly swollen, subhyaline, smooth, walls unthickened.

**Conidiophores** macronematous and micronematous, solitary, arising terminally or laterally from plagiobtropic or ascending hyphae, erect or subdecurrent, almost straight to more or less flexuous, cylindrical, sometimes geniculate towards the apex, but not nodulose, sometimes with short lateral prolongations at the apex, unbranched to once or twice branched (angle usually 30–45° degree, sometimes up to 90°), branches usually below a septum, 6–200 × (1–)2–4(–5) µm, septate, septa not very conspicuous, not constricted at the septa, subhyaline to pale brown, almost smooth to usually asperulate, walls unthickened or almost so.

**Conidiogenous cells** integrated, terminal or intercalary, sometimes conidiophores reduced to conidiogenous cells, cylindrical, sometimes geniculate, non-nodulose, 6–40 µm long, proliferation sympodial, with several conidiogenous loci often crowded at the apex and sometimes also at a lower level, situated on small lateral shoulders, unilateral swellings or prolongations, with up to 6(–10) denticulate loci, forming sympodial nodi of pronounced scars, intercalar conidiogenous cells with short or somewhat long lateral outgrowths, short denticulate-like or long branches with several scars at the apex, usually below a septum, loci protuberant, 1–1.5(–2) µm diam, thickened and darkened-refractive. **Ramoconidia** sometimes occurring, cylindrical, up to 32 µm long, 2.5–4 µm wide, with a broadly truncate, unthickened base, about 2 µm wide. **Conidia** catenate, formed in branched chains, straight, small terminal conidia globose, subglobose, ovoid, oval, 3–6 × 2.5–3.5 µm [av. ± SD, 4.5 (± 1.3) × 2.8 (± 0.4) µm], asperate, asperulate, with 0–2 distal hila, intercalar conidia and secondary ramoconidia ellipsoid-ovoid, ellipsoid to subcylindrical, 3.5–20(–28) × (2.5–)3–5(–6) µm [av. ± SD, 12.4 (± 5.4) × 4.1 (± 0.7) µm], 0–1-septate, rarely with up to three septa, sometimes slightly constricted at the septa, subhyaline, pale brown to medium olivaceous-brown, asperate or verruculose (muricate, granulate or colliculate under SEM), walls unthickened or slightly thickened, apex rounded or slightly to distinctly attenuated towards apex and base, often forming several apical hila, up to 7(–9), crowded, situated on small lateral outgrowths giving them a somewhat irregular appearance, hila protuberant, 0.5–1.5 µm diam, thickened and darkened-refractive; microcyclic conidiogenesis sometimes occurring.

**Cultural characteristics**: Colonies on PDA reaching 27–34 mm diam after 14 d at 25 ºC, smoke-grey, grey-olivaceous to olivaceous-grey, olivaceous-grey to iron-grey reverse, velvety to powdery, margin regular, entire edge, narrow, colourless to white, aerial mycelium absent or sparingly formed, felt, whitish, growth regular, flat, radially furrowed, with folded and elevated colony centre, deep into the agar, with age forming few to numerous prominent exudates, sporulation profuse, few high conidiophores formed. Colonies on MEA reaching 25–44 mm diam after 14 d at 25 ºC, olivaceous-grey to olivaceous- or iron-grey due to abundant sporulation in the colony centre, velvety, margin regular, entire edge, narrow, colourless, white to pale olivaceous-grey, aerial mycelium loose, diffuse, growth convex with papillate surface, radially furrowed, wrinkled, without prominent exudates, sporulating. Colonies on OA reaching 23–32 mm diam after 14 d at 25 ºC, grey-olivaceous, olivaceous-

**Cladosporium tenellum** K. Schub., Zalar, Crous & U. Braun, **sp. nov.** MycoBank MB504581. Figs 43–45.

**Etymology**: Refers to its narrow conidiophores and conidia.

---

**Fig. 45. Cladosporium tenellum (CPC 12053). A. A bird's eye view of a colony of Cladosporium with its very characteristic bundles of aerial hyphae. Numerous conidia are visible, formed on simple conidiophores. B. Hyphae that run on the agar surface give rise to conidiophores and numerous conidia, that are relatively rounded. C. Conidiophore ends are rather simple and have large scars. D. Hila on a secondary ramoconidium. Scale bars: A = 20 µm, B = 10 µm, C, E = 2 µm, D = 5 µm.**

and substrates. Besides these strains, several additional isolates listed under excluded strains are morphologically indistinguishable from *C. subtilissimum* in culture, but genetically different, clustering in various subclades. They are indicated as *Cladosporium* sp. in the tree (Fig. 3).

---

www.studiesinmycology.org

149
grey to olivaceous due to abundant sporulation in the colony centre, olivaceous- or iron-grey reverse, velvety, margin regular, entire edge, narrow, colourless or white, aerial mycelium sparse, diffuse, floccose, growth flat to low convex, radially furrowed, wrinkled, without prominent exudates, sporulation profuse.

**Substrates and distribution:** Hypersaline water and plant material; Israel, U.S.A.

**Notes:** *Cladosporium subtilissimum* and *C. cladosporioides* are morphologically comparable with the new species *C. tenellum*, but *C. cladosporioides* deviates in having usually smooth conidiophores and conidia with only few conidiogenous loci and conidial hila crowded at the apex and somewhat wider conidiophores, 3–5(–6) µm; and in *C. subtilissimum* the small terminal conidia are not globose but rather narrowly obvoid to limoniform, the conidiogenous loci and conidial hila are somewhat wider, (0.5–)0.8–2(–2.2) µm, and at the apices of conidiophores and conidia only few scars are formed.

*Cladosporium ramotenellum*, which morphologically also resembles *C. tenellum*, possesses longer and narrower, 0–3-septate conidia, 2.5–35 × 2–4(–5) µm, but forms only few conidiogenous loci and conidial hila at the apices of conidiophores and conidia.

**Basionym:** *Heterosporium variabile* Cooke, Grevillea 5(35): 123. 1877.

≡ *Cladosporium subnodosum* Cooke, Grevillea 17(83): 67. 1889.
Fig. 48. Cladosporium variabile (CPC 12753). A. Survey of hyphae that grow on the agar surface. Some of the fungal cells have a swollen appearance and could develop into a "foot cell" that gives rise to a conidiophore. B. A number of aerial hyphae obstruct the swollen, large structures on the agar surface, which give rise to conidiophores. Some of them appear ornamented. C. A series of conidia formed on a conidiophore (bottom of the micrograph). D. Detail of the ornamented conidia. The ornamentations are isolated and dispersed. Note also the ornamentation-free scar zone and the hilum of the left cell. E. Two conidia behind an aerial hypha. F. Two conidiophores forming secondary ramoconidia. Note the bulbous shape of the spore-forming apparatus. This micrograph is from an uncoated sample. Scale bars: A–C, F = 10 µm, D = 2 µm, E = 5 µm.

Daviellae tassianae similis, sed ascosporis maioribus, (22–)26–30(–35) × (7–)7.5–8(–9) µm, et ascis latioribus, plus quam 18 µm.

Ascomata pseudothecial, black, superficial, situated on a small stroma, globose, up to 250 µm diam, with 1–3 ostiolate necks; ostioles periphyseate, with apical periphysoids present; wall consisting of 3–6 layers of dark brown textura angularis, textura epidermoidea in surface view. Asci fasciculate, bitunicate, subcylindrical, obovoid to broadly ellipsoid, straight to slightly curved, 8-spored, 70–95 × 18–28 µm; with pseudoparenchymatal cells of the hamathecium persistent. Ascospores tri- to multiseriate, overlapping, hyaline, with irregular lumina, thick-walled, straight to slightly curved, fusoid-ellipsoidal with obtuse ends, widest near the middle of the apical cell, medially 1-septate, not to slightly constricted at the septum, at times developing a second septum in each cell, several ascospores with persistent, irregular mucoid sheath, (22–)26–30(–35) × (7–)7.5–8(–9) µm.

Mycelium immersed and superficial, irregularly branched, aerial mycelium twisted and spirally coiled, 1–3 µm wide, septate, sometimes with swellings or small lateral outgrowths, hyaline to subhyaline, smooth, walls unthickened, hyphae which give rise to conidiophores somewhat wider, 3–4.5 µm, subhyaline to pale brown, almost smooth to minutely verruculose, sometimes enveloped by a polysaccharide-like cover. Conidiophores usually macronematous, but also micromematous, arising terminally from ascending hyphae or laterally from plagiotropous hyphae. Macronematous conidiophores erect, more or less straight to flexuous, often distinctly geniculate-sinusiform forming lateral shoulders or unilateral swellings, sometimes zigzag-like or somewhat coralloid, nodulose, swellings at first terminal, then becoming lateral due to sympodial proliferation, often as distinct lateral shoulders, unbranched, sometimes once branched, 6–180 × (2.5–)3–6 µm, swellings (3–)6–11 µm wide, septate, not constricted at the septum, pale to medium olivaceous-brown or brown, usually verruculose, walls somewhat thickened, about 1 µm thick, sometimes appearing to be two-layered. Conidiogenous cells integrated, terminal and intercalary, cylindrical, nodulose to nodose,
with a single or two swellings per cell, swellings apart from each other or formed in short succession, loci confined to swellings, up to six per node, protuberant, 1–2 µm diam, thickened and darkened-refractive. Micronematous conidiophores erect, straight to slightly flexuous, unbranched, usually without swellings, filiform to narrowly cylindrical, sometimes only as short lateral outgrowths of hyphae, often almost indistinguishable from hyphae, up to 50 µm long, 1.5–2.5(–3) µm wide, longer ones plurisepitate, septa appear to be somewhat more darkened, with very short cells, 4–12 µm long, subhyaline to pale brown, smooth, walls unthickened or almost so. Conidiogenous cells integrated, usually terminal, rarely intercalary, cylindrical, non-nodulose, with a single, two or few conidiogenous loci at the distal end, protuberant, up to 2 µm diam, thickened and darkened-refractive. Conidia catenate, in branched chains, straight, subglobose, obovoid, oval, broadly ellipsoid to cylindrical, sometimes clavate, 4–26(–30) × (3.5–)5–9(–10) µm [av. ± SD, 16.8 (± 6.9) × 6.5 (± 1.4) µm], 0–3-septate, usually not constricted at the septa, septa becoming sinuous with age, often appearing to be darkened, pale to medium or even dark brown or olivaceous-brown, verrucose to densely verrucose or echinulate (granulate under SEM), walls slightly to distinctly thickened in larger conidia, apex and base broadly rounded, sometimes broadly truncate or somewhat attenuated, apex and base often appear to be darkened or at least reafctic, hila protuberant to somewhat sessile (within the outer wall ornamentation), (0.8–)1–2 µm diam, thickened and darkened-refractive; micrlecyclic conidiogenesis occurring.

Cultural characteristics: Colonies on PDA attaining 29 mm diam after 14 d at 25 ºC, olivaceous to olivaceous-grey or iron-grey, iron-grey or olivaceous-grey reverse, velvety to powdery, margin regular, entire edge to fimbriate, almost colourless, aerial mycelium whitish turning olivaceous-grey, sometimes reddish, greyish rose, woolly-felt, growth flat with elevated colony centre, somewhat folded or radially furrowed, with age forming several very small but prominent exudates, sporulation profuse. Colonies on MEA attaining 27 mm diam after 14 d at 25 ºC, olivaceous-grey to iron-grey, white to pale olivaceous-grey in the centre due to abundant aerial mycelium, velvety, margin very narrow, colourless, more or less entire edge, radially furrowed, aerial mycelium fluffy to floccose, dense, growth low convex with wrinkled and folded centre, without exudates, sporulation profuse. Colonies on OA attaining 25 mm diam after 14 d at 25 ºC, iron-grey or olivaceous-grey, margin regular, entire edge, narrow, white, glabrous, aerial mycelium whitish, at first mainly in the colony centre, high, dense, floccose, growth flat, abundantly sporulating, no exudates.

Substrate and distribution: Leaf-spotting fungus on Spinacia oleracea; Asia (China, India, Iraq, Pakistan), Europe (Austria, Belgium, Cyprus, Denmark, France, Germany, Great Britain, Hungary, Italy, Montenegro, Netherlands, Norway, Romania, Spain, Turkey), North America (U.S.A.).

Notes: In vivo the conidia are usually longer, somewhat wider and more frequently septate, (6.5–)10–45(–55) × (4.5–)6–14(–17) µm, 0–4(–5)-septate (Schubert 2005). In culture the dimensions tend to be smaller, which was already mentioned by de Vries (1952).

This leaf-spotting fungus superficially resembles C. macrocarpum, but besides its pathogenicity to Spinacia, C. variabile differs from the latter species in having distinctly larger and more frequently septate conidia on the natural host, forming twisted and spirally coiled aerial mycelium in culture and in having lower growth rates in culture (29 mm after 14 d on PDA versus 38 mm on average in C. macrocarpum). Furthermore, the conidial septa of C. variabile are often distinctly darkened, become sinuous with age and the apex and base of the conidia often appear to be distinctly darkened. A Davidiella teleomorph has not previously been reported for this species.

The cladosporioides complex

This species complex will be treated in an additional paper in this series, dealing with the epitypification of this common and widespread species, and with numerous isolates identified and deposited as C. cladosporioides.

DISCUSSION

In the present study, a multilocus genealogy supported by light and SEM microscopy, and cultural characteristics was used to redefine species borders within Cladosporium, especially within the C. herbarum complex. Most of the diagnostic features used for species delimitation on host material (Heuchert et al. 2005, Schubert 2005), proved to be applicable in culture. However, morphological features were often more pronounced in vitro than in vivo. For instance, conidiophore arrangement is not applicable to cultures, conidiophore and conidium widths were often narrower in culture than on the natural host, and macro- as well as microconidiophores were often observed in culture, but not on host material. All species belonging to the C. herbarum complex are characterised by possessing conidia which are ornamentated, the ornamentation ranging from minutely verrucose to verrucose, echinulate or spiny whereas in the C. sphaerospermum complex species with both smooth-walled as well as ornamented conidia are included (Zalar et al. 2007). The surface ornamentation varies based on the length of surface protuberances and in the density of ornamentation. Furthermore, the conidia are mainly catenate, formed in unbranched or branched chains. However, species previously referred to the genus Heterosporium, which usually produce solitary conidia or unbranched chains of two or three conidia at the most on the natural host, also belong to this species complex (e.g., C. iridis). In vitro these chains can become longer and may even be branched. The conidiophores formed in culture are mostly macro- but may also be micronematous, sometimes forming different types of conidia that vary in shape and size from each other. Most of the species possess nodulose conidiophores with the conidiogenesis confined to the usually lateral swellings. However, this phenetic trend is not consistently expressed in all of the species belonging to the C. herbarum complex. The various Cladosporium species within the C. herbarum complex were observed to have subtle differences in their phenotype which were visible by cryo-electron microscopy (cryoSEM), and are discussed below.

Fungal colonies: CryoSEM provides the opportunity to study the organisation of the fungal colony at relatively low magnifications. Cladosporium tenellum proved to be the only fungus able to form
aerial hyphal strands under the conditions studied. Cladosporium variabile formed abundant aerial hyphae, but in C. spinulosum these were sparse, and only conidiophores were observed on the agar surface. Three-day-old colonies of C. subinfatum formed numerous, long aerial hyphae, and no conidiophores could be discerned under the binocular. After 11 d the aerial hyphae seemed to have disappeared, giving rise to conidiophores. Cladosporium antarcticum, C. variabile and C. ramotenellum showed very large, swollen (> 10 μm) cells which gave rise to conidiophores. With C. variabile possible earlier stages of these cells were visible (Fig. 48), which gave rise to conidiophores. More than one conidiophore could be formed on such a structure (C. variabile and C. ramotenellum). Cladosporium herbarum has very wide hyphae on the agar surface, which gave rise to conidiophores as lateral branches. These wide hyphae were observed to anastomose, which may provide a firm interconnected supporting mycelium for these conidiophores. In C. herbaroides these wide hyphae could also be discerned, but conidiophore formation was less obvious. Similarly, C. tenellum has wide, parallel hyphae that gave rise to conidiophores.

These observations reveal fungal structures in Cladosporium that have not previously been reported on, and that raise intriguing biological questions. For instance, why are hyphal strands observed in some species (C. tenellum), and not in others, and what happens to the aerial hyphae during incubation in some species such as C. subinfatum? Furthermore, these preliminary results suggest that CryoSEM provide additional features that can be used to distinguish the different species in the C. herbarum complex.

Fine details of morphological structures: CryoSEM provides the opportunity to study fine details of the conidiophore, (ramo)conidia and scars. Samples can be studied at magnification up to × 8 000, revealing details at a refinement far above what is possible under the light microscope (LM) (Fig. 2). However, the LM micrographs provide information about the different compartments of ramoconidia, as well as the thickness and pigmentation of the cell wall of different structures. With other words, the different techniques are complementary, and both reveal fungal details that build up the picture that defines a fungal species.

Conidiophores can vary with respect to their width and the length. Cladosporium ramotenellum, C. antarcticum and C. variabile have tapered conidiophores formed on large globose “foot cells”. The conidiophore itself can be branched. Cladosporium spinulosum has conidiophores that rise from the agar surface, but can have a common point of origin. These conidiophores are not tapered, but parallel and slender. The conidiophores of C. bruheii and C. herbaroides are rather long, and can appear as aerial hyphae.

An important feature of the conidiophore is the location were the conidia are formed. Conidiophore ends can be simple and tubular, or rounded to more complex, several times geniculate, with several scars. Conidiophore ends become more elaborate over time. Cladosporium spinulosum and C. tenellum have nearly tubular conidiophore ends, with often very closely aggregated scars. The conidiophore ends of C. subinfatum are also near tubular with a hint of bulbousness. Cladosporium subtilissimum is similar, but with somewhat more elevated scars that look denticulate. Cladosporium variabile has nodulose, somewhat swollen apices with often sessile, almost inconspicuous scars. In the case of C. macrocarpum, these structures are also nodulose to nodose and somewhat bent, with only slightly protuberant loci. Cladosporium ramotenellum has tubular conidiophore ends with pronounced scars. Cladosporium antarcticum has very characteristic, tapered ends, and widely dispersed (5 μm) scars. More complex conidiophore ends are more irregular in shape, and have scars dispersed over a longer distance, such as observed in C. bruheii, C. herbaroides, and C. herbarum.

Secondary ramoconidia are usually the first conidia formed on a conidiophore. They are often multicellular, and have one basal cladosporioid hilum, and more at the apex. Few Cladosporium species additionally form true ramoconidia representing apical parts of the conidiophore which secede at a septum resulting in an undifferentiated non-corneous base and function as conidia. Ramification of conidial chains is realised through these conidia. They can occur in up to three stages, which results in elaborated spore structures. The basal secondary ramoconidium is invariably the largest, and cell size decreases through a series of additional secondary ramoconidia, intercalary conidia, and small, terminal conidia. The elongation of secondary ramoconidia varies among the different species. Cladosporium macrocarpum has broadly ellipsoidal secondary ramoconidia usually with broadly rounded ends, like C. variabile, while C. spinulosum has secondary ramoconidia that can often hardly be discerned from the conidia that are formed at later stages. The conidia of the other species roughly fall between these species. The most notable structures on these conidia are their ornamentation, scar pattern and morphology. Cladosporium spinulosum forms numerous globose to subsphaerical spores with digitate, non-tapered surface ornamentation, which is unique for all the species discussed here. In his study on Cladosporium wall ornamentation, David (1997) recognised three classes of echinulate surfaces (aculeate, spinulose, digitate), and five classes of verrucose surfaces (muricate, granulate, colliculate, pustulate and pedicellate) (Fig. 2). The ornamentation particles vary in shape, width, height and density. The most strongly ornamented conidia of the species examined by SEM are formed by C. ossifragi, with the ornamentation both large (up to 0.5 μm wide) and high, and can be regarded as densely muriately ornamented. Strong ornamentation is also seen in C. herbaroides, which is mostly granulate. Cladosporium tenellum (with muricate, granulate and colliculate tendencies) and C. bruheii (mostly granulate with some muricate projections) have relatively large ornamentation structures with slightly more space between the units than the other two species. Cladosporium antarcticum, C. ramotenellum, C. variabile and C. subtilissimum exhibit rather large granulate ornamentations that have a more irregular and variable shape. Cladosporium subinfatum shows the widest dispersed structures of the series, being muricate. In contrast, C. macrocarpum has a very neat and regular pattern of muricate ornamentation. The area of formation of new spores on conidia is invariably not ornamented, and hila all have the typical Cladosporium morphology with a central dome and a ring-like structure around it.

Branching patterns: Spores usually show a “line of weakness” between them where the coronate scars form. It seems that scars at both sides of the line of weakness have the central dome structure, which appears to play a major role in the effective mechanism Cladosporium employs for spore dispersal, with the dome actively pushing the conidia apart. This mechanism is also illustrated in David (1997, fig. 2E). Indeed, conidia of Cladosporium are very easily dislodged; even snap freezing or the electrical forces inside the SEM often result in dislodgement of the spores in a powdery “wave”. It is no surprise, therefore, that Cladosporium conidia are to be found in most air samples. In Cladosporium, conidia are mostly formed in chains, with the size invariably decreasing from the base to the apex of the row. Upon formation each conidium is separated from the conidiophore, or previously formed conidium, and hence from its nutrients. The basal ramoconidium or secondary ramoconidia have the nutrients and metabolic power to produce
a number of additional secondary ramoconidia that in turn could produce a chain of intercalary conidia, and finally, some small, single-celled, terminal conidia. Further research is still necessary to determine if specific branching patterns can be linked to different species.

A surprising finding from the present study is the huge diversity in species and genotypes that exist in nature, be it in the indoor environment, on fruit surfaces, or in extreme ecological niches such as salterns, etc. It is clear that detailed studies would be required to find and characterise other species of Cladosporium and obtain a better understanding of their host ranges and ecology. A further surprise lay in the fact that several of these species are capable of sexual reproduction, and readily form Davidiella teleomorphs in culture. The Davidiella states induced here were all from homothallic species. Further attention now needs to be given to elucidating teleomorphs from other species which, as in Mycosphaerella (Groenewald et al. 2006, Ware et al. 2007) could be heterothallic, and experiencing clandestine sex.

Despite the occurrence of many different genotypes in variable genes, the degree of diversity in the entire data set was low. For the majority of the species ITS was almost invariant, with only six genotypes in the entire dataset. This suggests a very recent evolution. The standardised index of association ($I^*$) was high (0.3914), indicating an overabundance of clonality and $I$ or inbreeding, the latter possibly matching with observed homothallism of Davidiella teleomorphs. Clonality was visualised with SplitsTree software, where star-shaped representations without any sign of reticulation were obtained for all genes, though at different branch lengths (Fig. 5). With STRUCTURE software an optimal subdivision was achieved at six putative groups. Some of them were distinctly separated, yielding a theta ($\theta$) around 0.14, but in most cases there was considerable overlap in representation of motifs, with $\theta$ at significantly higher values. Results are difficult to interpret due to the small size of the data set compared to the number of predicted groups, and due to unknown but probably large sampling effects. With optimal subdivision of the 79 strains at a hypothesised value of $K = 6$ (Fig. 4), still a large degree of inter-group similarity was noted, as was the case at any other level of $K$. This was particularly obvious when data from the most variable genes (EF and ACT) are superimposed (Fig. 4). The ACT groups are further subdivided by EF data, but in many cases the same EF motif (indicated with arrows) was encountered in different (multilocus) species, for example in C. antarcticum, C. spinulosum, Davidiella spp., and the various clusters comprising Cladosporium strains which are phenotypically almost indistinguishable but genetically distinct from C. subtilissimum. A similar situation was found with the distribution of EF genotypes (indicated with doughnuts) in C. herbarum and C. macrocarpum. Nevertheless, the data set showed significant structuring, partly correlating with geography, e.g. the EF-determined cluster of C. bruennii that contained isolates from different sources in The Netherlands. Differences may be over-accentuated by known sampling effects, particularly in C. herbarum and C. macrocarpum, where single-spore isolates from a single collection are included.

Taken together the data suggest a recent, preponderantly clonal evolution, combined with limited natural selection at a low level of evolutionary pressure. As a result, many genotypes produced by hot spots in the genes analysed have survived, leading to nearly random variation in the data set. Many combinations of motifs that possibly could emerge have maintained in the course of time due to the absence of recombination. This indicates that the observed structure is that of populations within a single species, and consequently a distinction of clonal “species” could be redundant.

This conclusion is underlined by the fact that a single source in a single location can be colonised by various genotypes, such as grapes in the U.S.A. containing three different, closely related genotypes. However, the phenomenon of co-inhabitation by different Mycosphaerella species on the same lesion of Eucalyptus has been described before (Crous 1998, Crous et al. 2004) and it is therefore not surprising that different genotypes occurring close together are also observed for the related genus Cladosporium. There is no obvious ecological difference between genotypes, and hence isolates seem to have equal fitness.

However, in general we noticed a remarkable concordance of genetic and phenetic characters. The morphological study was done prior to sequencing, and nearly all morphotypes clustered in separate molecular entities. There are some exceptions, such as with C. antarcticum with striking morphology that was almost identical on the molecular level to Cladosporium spp. that resemble C. subtilissimum and would normally have been interpreted to be a mutant. Conversely, nearly all genetically distinguishable groups proved to be morphologically different, with the exception of members of the C. subtilissimum s. lat. complex (indicated as Cladosporium sp. in Fig. 3 and Table 1). The possibility remains that the found genetic parameters correlate with phenetic markers other than morphology, such as virulence, toxins or antifungal susceptibilities. For this reason we introduce the established entities here as formal species. They can be diagnosed by ACT sequencing or by phenetic characters provided in the key. For simple routine purposes, however, they can be seen and treated as the “C. herbarum complex”, based on their close phylogenetic relationships.

ACKNOWLEDGEMENTS

Several colleagues from different countries provided material and valuable cultures without which this work would not have been possible. In this regard, we thank particularly Alina G. Greslebin (CIEFAP, Esquel, Chubut, Argentina), Frank Dugan and Lindsey DuToit (Washington State Univ., U.S.A.), and Annette Ramaley (Colorado, U.S.A.). Konstanze Schubert was financially supported by a Synthesys grant (No. 2559) which is gratefully acknowledged. We thank Marjan Vermaas for preparing the photographic plates, Rianne van Dijken for the growth studies, and Arien van Ieperen for maintaining the cultures studied. Bert Gerrits den Van den Ende is acknowledged for assisting with the molecular data analyses.
